1. Change History

Version 1.11 – Editor: Robert Shapiro (rshapiro@capevisions.com)
- Added Discussion and attribute tables for the seven application types. (Contributed by TIBCO).

Version 1.10 – Editor: Robert Shapiro (rshapiro@capevisions.com)
- Added the Application Type and seven elements under Type..
- Changed DiagramRef to PackageRef.
- Both Tool and Subflow now have PackageRef.
- Both Tool and SubFlow now have a choice of ActualParameters or DataMappings.
- Tool is now under Task, and it was renamed to TaskApplication.
- Subflow was deprecated and renamed to ProcessRef in XPDL 2.0 (Note that TriggerResultLink has an attribute called also ProcessRef, so this may introduce some confusion).
- PoolId and LaneId were removed from Activity and Artifact.
- LaneId was added to NodeGraphicsInfo.
- NodeGraphicsInfo now has Extended Attributes.
- StartMode/FinishMode moved to activity attributes.
- Metamodels updated to reflect changes (e.g. Tool now under task)
- Removed initial ‘t’ from all schema type definitions
- Added Length, Precision andScale Attributes to BasicType element.

Version 1.09 – Editor: Robert Shapiro (rshapiro@capevisions.com)
- Minor Typos fixed.
- toolId attribute replaced by ToolId
- Target attribute type changed to NMTOKEN
- All schema inserts updated for new approach to Deprecation using name spaces.

Version 1.08 – Editor: Mike Marin (mmarin@filenet.com)
- Enhanced document and schema with new extended attributes model.
- Schema types are now prefixed with ‘t’.
- Changed ExternalPackage id to Id to be compatible with all other Ids.
- Normalized Name and Id attributes for all entities that require them.
- Changed Assignment to have Target and Expression entities.
- Changed TaskScript to be any arbitrary expression.
- Introduced a ExpressionType type and used for all expressions
- Updated all the sections with schema
- Added a section on XPDL version 1.0 compatibility

Version 1.07 – Editor: Robert Shapiro (rshapiro@capevisions.com)
- Includes changes based on XPDL 1.0 requests
• Formal parameter index deprecated.
• AccessLevel attribute of Process made optional with default PUBLIC.
• Additional attribute for subflow provides name of datafield in which to store instantiation id.
• Execution attribute for subflow is optional with default SYNCHR.
• GraphConformance attribute for Conformance class is optional with default NON_BLOCKED.
• Transition condition may have at most one child element expression.
• Tool attribute ‘type’ deprecated: no longer needed since there are no constructs for declaring Procedures or any information about their formal parameters or parameter passing. Hence all Tools should be Applications.
• DeadlineCondition deprecated. DeadlineDuration element introduced with type = string.

Version 1.06 – Editor: Robert Shapiro (rshapiro@capevisions.com)
• Includes all editing changes from Justin Brunt (JBrunt@staffware.com).

Version 1.05 – Editor: Robert Shapiro (rshapiro@capevisions.com)
• Minor Changes to Schema: ProcessType – order of elements to preserve compatibility with XPDL 1.0
• Minor typos.
• Instantiate attribute removed from TaskSend and TaskService. TaskSend Message documentation fixed.
• Explanation of OTHERWISE clause changed for SPLITs. Corrected documentation on Splits and Joins to reflect BPMN extensions. Added documentation in Route Activity section.
• Package reference extended to include type declarations.
• Added attribute to External Package Reference.
• Added reference to external packages for Participant identifiers.

Version 1.04 – Editor: Robert Shapiro (rshapiro@capevisions.com)
• Minor Changes to Schema: order of elements and some elements made optional.
• Examples of Gateways and Events

Version 1.03 – Editor: Robert Shapiro (rshapiro@capevisions.com)
• Inserted text explanations of BPMN constructs used in meta-models.
• Updated individual schema sections and tables, adding sections for all elements

Version 1.02 – Editor: Mike Marin (mmarin@filenet.com)
• Reorganized document and added new meta-models

Version 1.01 – Editors: Mike Marin (mmarin@filenet.com) and Robert Shapiro (rshapiro@capevisions.com)
• Initial draft of bidirectional mapping to BPMN 1.0

Version 1.0 – Editor: Roberta Norin (robertan@attbi.com).

1.1. Acknowledgements

XPDL2.0 required many hours of work by individuals who had to find time to contribute while carrying out their normal duties for the companies that employ them.

Robert Shapiro (Global 360) and Mike Marin (FileNET) did the bulk of the work.
Justin Brunt, Wojciech Zurek, Tim Stephenson (Staffware/TIBCO) , Sasa Bojanic (Prozone) and Gangadhar Gouri (Fujitsu Software) made significant contributions.
Keith Swensen (Fujitsu Software) provided invaluable organizational support and encouragement.
2. **Audience**

The intended audience for this document is primarily vendor organizations who seek to implement the XML Process Definition Language (XPDL) of the Workflow Management Coalition (WfMC), or using it as a file format for the Business Process Modeling Notation (BPMN) of the Business Process Management Initiative (BPMI). It may also be of interest to those seeking to assess conformance claims made by vendors for their products. Comments should be addressed to the Workflow Management Coalition.

3. **Purpose**

XPDL version 2.0 is back compatible with XPDL version 1.0, and is intended to be used as a file format for BPMN. The original purpose of XPDL is maintained and enhanced by this second version of the specification. The XPDL and the BPMN specifications address the same modeling problem from different perspectives. XPDL provides an XML file format that can be used to interchange process models between tools. BPMN provides a graphical notation to facilitate human communication between business users and technical users, of complex business processes.

There are a number of elements that are present in BPMN version 1.0 but were not present in XPDL version 1.0. Those had been incorporated into this version of XPDL.

The WfMC has identified five functional interfaces to a process or workflow service as part of its standardization program. This specification forms part of the documentation relating to “Interface one” - supporting Process Definition Import and Export. This interface includes a common meta-model for describing the process definition (this specification) and also a companion XML schema for the interchange of process definitions.

4. **Introduction**

A variety of different tools may be used to analyse, model, describe and document a business process. The process definition interface defines a common interchange format, which supports the transfer of process definitions between separate products.

The interface also defines a formal separation between the development and run-time environments, enabling a process definition, generated by one modelling tool, to be used as input to a number of different run-time products.

A process definition, generated by a build-time tool, is capable of interpretation in different run-time products. Process definitions transferred between these products or stored in a separate repository are accessible via the XPDL common interchange format.

To provide a common method to access and describe process definitions, a process definition meta-data model has been established. This meta-data model identifies commonly used entities within a process definition. A variety of attributes describe the characteristics of this limited set of entities. Based on this model, vendor specific tools can transfer models via a common exchange format.

One of the key elements of XPDL is its extensibility to handle information used by a variety of different tools. XPDL may never be capable of supporting all additional information requirements in all tools. Based upon a limited number of entities that describe a process definition (the "Minimum Meta Model"), XPDL supports a number of differing approaches.

One of the most important elements of XPDL is a generic construct that supports vendor specific attributes for use within the common representation. We recommend that any missing attributes be proposed to the WfMC interface one workgroup for inclusion in future releases.

This document describes the meta-model, which is used to define the objects and attributes contained within a process definition. The XPDL grammar is directly related to these objects and attributes. This approach needs two operations to be provided by a vendor:

- Import a process definition from XPDL.
- Export a process definition from the vendor's internal representation to XPDL.
A vendor can use an XSL style sheet to accomplish these two operations.

All keywords and terms used within this specification are based upon the WfMC Glossary, or terminology used by BPMN.

For the purpose of this document, the terms process definition, business process model, and workflow model are all considered to represent the same concept, and therefore, they are used interchangeably.

4.1. Conformance

A vendor can not claim conformance to this or any other WfMC specification unless specifically authorised to make that claim by the WfMC. WfMC grants this permission only upon the verification of the particular vendor’s implementation of the published specification, according to applicable test procedures defined by WfMC.

Conformance for process definition import / export is essentially based upon conformance to the XPDL grammar. However, there is a mandatory minimum set of objects, as specified within this document, which must be supported within XPDL. But, given the wide variation of capabilities in modelling tools, it is reasonable to assume that an individual tool might conform to this specification but not be able to swap complete definitions with all other conforming products. A product that claims conformance must generate valid, syntactically correct XPDL, and must be able to read all valid XPDL.

4.2. XPDL Version 1.0 Compatibility

XPDL version 2.0 is compatible with XPDL version 1.0, with minor exceptions. The XPDL schema version 2.0 has a different namespace, and tools wishing to be compatible with XPDL version 1.0 need to understand both XPDL 1.0 and XPDL 2.0 namespaces.

The following XPDL version 1.0 elements have been deprecated in version 2.0:

- BlockId attribute of BlockActivity element. Replaced by ActivitySetId.
- DeadlineCondition element. Replaced with DeadlineDuration.
- Index attribute in FormalParameter element. Because, FormalParameters must match the order in the declaration, and so there is no need for Index.
- Type attribute of Tool element. Because tools are applications and so this attribute is not necessary. (Tools cannot be procedures - from WPDL - because XPDL does not provide any way of defining the formal parameters for procedures.) Note also that Tool is a type of Task: TaskApplication.
- Xpression element in Condition element. Replaced by Expression.
- The order in a WorkflowProcess changed from DataFields, Participants, and Applications to be Participants, Applications, and DataFields. This makes the order in Process and package consistent.

4.3. References

The following documents are associated with this document and should be used as a reference.

General background information:

WfMC, Terminology & Glossary (WfMC-TC-1011)
WfMC, Reference Model (WfMC-TC-1003)
WfMC, API specifications, which include process definition manipulation APIs:
WfMC, Client Application API Specifications (WAPI) (WfMC-TC-1009)
5. Overview of Process Definition Interchange

An XPDL package corresponds to a Business Process Diagram (BPD) in BPMN, and consists of a set of Process Definitions. The WfMC defines a process as:

The representation of a business process in a form that supports automated manipulation, such as modeling, or enactment by a workflow [or business] management system. The process definition consists of a network of activities and their relationships, criteria to indicate the start and termination of the process, and information about the individual activities, such as participants, associated IT applications and data, etc. (WfMC Glossary - WfMC-TC-1011)

The process definition provides an environment for a rich description of a process that can be used for the following,

- Act as a template for the creation and control of instances of that process during process enactment.
- For simulation and forecasting.
- As a basis to monitor and analyse enacted processes.
- For documentation, visualization, and knowledge management.

The process definition may contain references to subflows, separately defined, which make up part of the overall process definition.

An initial process definition will contain at least the minimal set of objects and attributes necessary to initiate and support process execution. Some of these objects and attributes will be inherited by each created instance of the process.

The WfMC Glossary also contains descriptions of, and common terminology for, the basic concepts embodied within a process definition such as activities, transitions, relevant data and participants, etc.

5.1. Approaches to Process Definition Interchange

This specification uses XML as the mechanism for process definition interchange. XPDL forms a common interchange standard that enables products to continue to support arbitrary internal representations of process definitions with an import/export function to map to/from the standard at the product boundary.

A variety of different mechanisms may be used to transfer process definition data between systems according to the characteristics of the various business scenarios. In all cases the process definition must be expressed in a consistent form, which is derived from the common set of objects, relationships and attributes expressing its underlying concepts.

The principles of process definition interchange are illustrated in Figure 5-1: The Concept of the Process Definition Interchange.
Figure 5-1: The Concept of the Process Definition Interchange
6. Meta-Model

The Meta-Model describes the top-level entities contained within a Process Definition, their relationships and attributes (including some which may be defined for simulation or monitoring purposes rather than for enactment). It also defines various conventions for grouping process definitions into related process models and the use of common definition data across a number of different process definitions or models.

6.1. Processes and Packages

The process model includes various entities whose scope may be wider than a single process definition. In particular the definitions of participants, applications and relevant data may be referenced from a number of process definitions. The meta-model assumes the use of a common process definition repository to hold the various entity types comprising the process definition. Within the repository itself and to support the efficient transfer of process definition data to/from the repository, the concept of a package is introduced, which acts as a container for the grouping of common data entities from a number of different process definitions, to avoid redefinition within each individual process definition.

The package provides a container to hold a number of common attributes from the process definition entity (author, version, status, etc.). Each process definition contained within the package will automatically inherit any common attributes from the package, unless they are separately re-specified locally within the process definition.

An XPDL Package corresponds to a BPMN Business Process Diagram. At the level below Package, there are four new elements which are discussed in the sequel:

1. **Pools** (and their lanes) are associated with processes and are used in layout and to define participants for the sequence flow elements contained within.

2. **Message flows** are used to represent communication between processes, based on Web Services Description Language (WSDL) protocols.

3. **Associations** and **Artifacts** are used to document the process definitions. Associations and the Artifacts they connect to provide additional information for the reader of a BPMN Diagram, but do not directly affect the execution of the Process.

Within a package, the scope of the definitions of some entities is global and these entities can be referenced from all process definitions (and associated activities and transitions) contained within the package. Those entities are:

- participant specification
- application declaration, and
- relevant data field

The package reference allows the use within the package or its contained objects of references to top-level entities in the referenced external package:

- Process ids for subflow reference
- participant specifications
- application declarations
- type declarations

Conventions on name and identifier management across different packages within the same repository address space to achieve any necessary global uniqueness are for user/vendor definition. The assumed convention during process enactment is that name reference searches follow the sequence:

- Process ids - firstly within the same model (including any references to process definitions for remote execution on a different service), then within any externally referenced model
- Applications / participants - firstly within the same model, then within any externally referenced model

Relevant data naming must be unique within a package; where such data is passed between processes as parameters the convention at this version of specification is that copy semantics will be used. Responsibility rests with process
designers/administrators to ensure consistent name/data type usage within process definitions/models to support subflow operations (including any required remote process interoperability).

6.2. Package Meta-Model

- Multiple process definitions are bound together in a model definition. The Package acts as a container for grouping together a number of individual process definitions and associated entity data, which is applicable to all the contained process definitions (and hence requires definition only once).

![Package Definition Meta Model](image)

The meta-model for the Package identifies the entities and attributes for the exchange, or storage, of process models. It defines various rules of inheritance to associate an individual process definition with entity definitions for participant specification, application declaration and relevant data field, which may be defined at the package level rather than at the level of individual process definitions.

The Package Definition allows the specification of a number of common process definition attributes, which will then apply to all individual process definitions contained within the package. Such attributes may then be omitted from the individual process definitions. (If they are re-specified at the level of an individual process definition this local attribute
value takes precedence over the global value defined at the package level.

6.2.1. Process Repository

The process definition import/export interface is assumed to operate to/from a definition repository of some form associated with the process or workflow management system. The import/export interface is realized by the transfer of files containing XPDL into or out of such repository. This interface specification allows the import or export of process definition data at the level of individual process definitions and packages.

The internal interface between the repository and control functions is specific to individual vendor products and does not form part of this standard. It is assumed that separation is provided (for example by version control) between repository usage as a static repository (for persistent, ongoing storage of process definition data) and any dynamic usage (for managing changes to the process execution of extant process instances).

The local storage structure of the process definition repository is not part of the WfMC standard. The use of a package is defined only as an aid to simplify the import/export of reusable data structures. Where a simple process repository structure is used, operating at a single level of process definition, shared information within an imported package may be replicated into each of the individual process definitions at the import interface (and similarly repacked, if required, for process definition export).

6.2.1.1. Redefinition and Scope

The possibility of redefining attributes and meta-model entities and referencing external packages introduces the principles of scope and hierarchy into the XPDL (and process repository) structures.

   (i) Relevant data field

   Process relevant data field has a scope that is defined by the directly surrounding meta-model entity and is not nested. The visibility of its identifier is also defined by that entity.

   (ii) Attributes

   Attributes including extended attributes have a scope that is defined by the directly surrounding meta-model entity and are nested, i.e. may be redefined at a lower level. Example: The name attribute is redefined in each entity definition. The visibility of extended attribute identifiers is within the particular entity and all sub-entities unless the identifier is redefined in a sub-entity.

   (iii) Participants and applications

   • Participants and applications have a scope and visibility equivalent to extended attributes. All referenced relevant data field and extended attributes have to be defined in the scope where they are used, at least in the same package.

   For a referenced external package entity that needs itself reference to entities and their identifiers defined in its external package clause the mechanism is started with the root in that package. That guarantees that no conflict takes place if the invoking process has an entity with the same id, which the definer of the referenced package cannot be aware of.

   The described mechanism of external package provides high flexibility for designers and administrators. One can separate organization descriptions (participant entities) and process definitions in separate models, one can add a new release of a process description or add a new process definition sharing the rest of the definition of previously defined and exchanged models without resubmitting the whole context etc.
6.3. Process Meta-Model

The meta-model identifies the basic set of entities and attributes for the exchange of process definitions. For a Process Definition the following entities must be defined, either explicitly at the level of the process definition, or by inheritance directly or via cross reference from a surrounding package.

![Process Definition Meta Model Diagram]

These entities contain attributes that support a common description mechanism for processes. They are described in the subsequent document sections.

The XPDL Process and WorkflowProcess correspond to the BPMN Process. At the level below Process, there are three new elements: Assignments, Properties and Categories; these are discussed in the sequel. Assignments allow properties to be assigned values in the course of execution of a Process. Categories are useful in reporting and analysis of running Processes but do not affect the behavior of the processes.
6.4. Entities Overview

The meta-model identifies the basic set of entities used in the exchange of process definitions. The top-level entities are as follows:

6.4.1. Swimlanes

Swimlanes are used to facilitate the graphical layout of a collection of processes and may designate participant information at the process level and performer information at the activity level. The Swimlane structure is depicted by a collection of non-overlapping rectangles called Pools. Each Pool may be further subdivided into a number of Lanes.

6.4.1.1. Pool

A Pool acts as the container for flow objects (activities) and Sequence Flow (transitions) between them. The Sequence Flow may cross the boundaries between Lanes of a Pool, but cannot cross the boundaries of a Pool. The interaction between Pools, e.g., in a B2B context, is shown through Message Flow.

Another aspect of Pools is whether or not there is any activity detailed within the Pool. Thus, a given Pool may be shown as a “White Box,” with all details exposed, or as a “Black Box,” with all details hidden. No Sequence Flow is associated with a “Black Box” Pool, but Message Flow can attach to its boundaries.

Each page of the diagram is regarded as an invisible ‘background pool’. Activities and sequence flow not within an explicit Pool are treated as contained by the background pool.

6.4.1.2. Lane

Lanes are used to subdivide a Pool. All the activities within a Lane may inherit one or more properties from the Lane. A typical use of this is to give the Lanes ‘role names’ and have the Activities inherit these role names as ‘Participant assignment/Performer expressions’.

6.4.2. Process Definition

The Process Definition entity provides contextual information that applies to other entities within the process. It is a container for the process itself and provides information associated with administration (creation date, author, etc.) or to be used during process execution (initiation parameters to be used, execution priority, time limits to be checked, person to be notified, simulation information, etc.).

6.4.3. Process Activity

A process definition consists of one or more activities, each comprising a logical, self-contained unit of work within the process. An activity represents work, which will be performed by a combination of resource (specified by participant assignment) and/or computer applications (specified by application assignment). Other optional information may be associated with the activity such as information on whether it is to be started / finished automatically by the process or workflow management system or its priority relative to other activities where contention for resource or system services occurs. Usage of specific relevant data field items by the activity may also be specified. The scope of an activity is local to a specific process definition (although see the description of a subflow activity below).

In addition to the tools explicitly declared as applications, an activity may be implemented as one of a number of built-in BPMN tasks. Most of these concern B2B messaging. Their attribute details are discussed in the sequel.

An activity may be a subflow - in this case it is a container for the execution of a (separately specified) process definition, which may be executed locally within the same service, or (possibly using the process interoperability interface) on a remote service. The process definition identified within the subflow contains its own definition of activities, internal transitions, resource, and application assignments (although these may be inherited from a common source). In- and out-parameters permit the exchange of any necessary relevant data field between calling and called process (and, where necessary, on return). Such definitions are equivalent to BPMN independent subprocesses.

An activity may be a block activity that executes an activity set, or map of activities and transitions. Activities and transitions within an activity set share the name space of the containing process. An activity set is equivalent to a
BPMN embedded subprocess.

An activity may be a route activity, which performs no work processing (and therefore has no associated resource or applications), but simply supports routing decisions among the incoming transitions and/or among the outgoing transitions. BPMN gateways are represented by Route activities.

Finally, an activity may represent a BPMN event. An event is something that “happens” during the course of a business process. These events affect the flow of the process and usually have a cause (trigger) or an impact (result). There are three types of Events, based on when they affect the flow: Start, Intermediate, and End. Their attribute details are discussed in the sequel.

### 6.4.4. Transition Information

Activities are related to one another via flow control conditions (transition information). Each individual transition has three elementary properties, the from-activity, the to-activity and the condition under which the transition is made. Transition from one activity to another may be conditional (involving expressions which are evaluated to permit or inhibit the transition) or unconditional. The transitions within a process may result in the sequential or parallel operation of individual activities within the process. The information related to associated split or join conditions is defined within the appropriate activity, split as a form of “post activity” processing in the from-activity, join as a form of “pre-activity” processing in the to-activity. This approach allows the control processing associated with process instance thread splitting and synchronization to be managed as part of the associated activity, and retains transitions as simple route assignment functions. The scope of a particular transition is local to the process definition, which contains it and the associated activities.

More complex transitions, which cannot be expressed using the simple elementary transition and the split and join functions associated with the from- and to-activities, are formed using route activities, which can be specified as intermediate steps between real activities allowing additional combinations of split and/or join operations. Using the basic transition entity plus route activities, routing structures of arbitrary complexity can be specified. Since several different approaches to transition control exist within the industry, several conformance classes are specified within XPDL. These are described later in the document.

### 6.4.5. Participant Declaration

This provides descriptions of resources that can act as the performer of the various activities in the process definition. The particular resources, which can be assigned to perform a specific activity, are specified as an attribute of the activity, participant assignment, which links the activity to the set of resources (within the participant declaration) which may be allocated to it. The participant declaration does not necessarily refer to a human or a single person, but may also identify a set of people of appropriate skill or responsibility, or machine automata resource rather than human. The meta-model includes some simple types of resource that may be defined within the participant declaration.

### 6.4.6. Application Declaration

This provides descriptions of the IT applications or interfaces which may be invoked by the service to support, or wholly automate, the processing associated with each activity, and identified within the activity by an application assignment attribute (or attributes). Such applications may be generic industry tools, specific departmental or enterprise services, or localized procedures implemented within the framework of the process or workflow management system. The application definition reflects the interface between the engine and the application or interface, including any parameters to be passed.

### 6.4.7. Artifact

To satisfy additional modeling concepts that are not part of the basic set of flow elements (activities, sequence and message flow), BPMN provides the concept of Artifacts that can be linked to the existing Flow Objects through Associations (see below). Thus, Artifacts do not affect the basic Sequence or Message Flow, nor do they affect mappings to execution languages.

At this point, BPMN provides three standard Artifacts: A Data Object, a Group, and an Annotation. Additional standard Artifacts may be added to the BPMN specification in later versions. A modeler or modeling tool may extend a BPD and add new types of Artifacts to a Diagram. Any new Artifact must follow the specified Sequence Flow and Message Flow connection rules.
6.4.8. Message Flow

A Message Flow is used to show the flow of messages between two participants/processes that are prepared to send and receive them. In BPMN, two separate Pools in the Diagram will represent the two participants/processes (e.g., business entities or business roles). All Message Flow must connect two separate Pools. They can connect to the Pool boundary or to Flow Objects within the Pool boundary. They cannot connect two objects within the same Pool.

6.4.9. Association

An Association is used to associate information and Artifacts with Flow Objects. Text and graphical non-Flow Objects can be associated with the Flow Objects and Flow. An Association is also used to show the activities used to compensate for an activity.

An Association does not have a specific mapping to an execution language element. These objects and the Artifacts they connect to provide additional information for the reader of the BPMN Diagram, but do not directly affect the execution of the Process.

6.4.10. Relevant data field

This defines the data that is created and used within each process instance during process execution. The data is made available to activities or applications executed during the process and may be used to pass persistent information or intermediate results between activities and/or for evaluation in conditional expressions such as in transitions or participant assignment. Relevant data field is of particular type. XPDL includes definition of various basic and complex data types, (including date, string, etc.) Activities, invoked applications and/or transition conditions may refer to process relevant data field.

6.4.11. Data Types and Expressions

The meta-model (and associated XPDL) assumes a number of standard data types (string, reference, integer, float, date/time, etc.); such data types are relevant to data fields, system or environmental data or participant data. Expressions may be formed using such data types to support conditional evaluations and assignment of new values to data fields. Data types may be extended using an XML schema or a reference to data defined in an external source.

6.4.12. System and Environmental Data

This is data which is maintained by the process or workflow management system or the local system environment, but which may be accessed by activities or used by the process or workflow management system in the evaluation of conditional expressions and assignments in the same way as relevant data fields.

6.4.13. Resource Repository

The resource repository accounts for the fact that participants can be humans, programs, or machines. In more sophisticated scenarios the participant declaration may refer to a resource repository, which may be an Organizational Model in the case of human participants. Note that this specification does not define or require a resource repository.

6.4.14. Vendor or User specific Extensions

Although the meta-model and associated XPDL contain most of the constructs, which are likely to be required in the exchange of process definitions, there may be circumstances under which additional information (user or vendor specific) will need to be included within a process definition. Users and vendors are encouraged to work as far as possible within the standard entity / attribute sets; however, when extensions are needed the XPDL schema provides a standard way to extend it with vendor or user specific extensions.

6.4.14.1. Extended Elements and Attributes

The primary method to support such extensions is by the use of extended attributes. Extended attributes are those
defined by the user or vendor, where necessary, to express any additional entity characteristics. XPDL schema supports namespace-qualified extensions to all the XPDL elements. The XPDL elements can be extended by adding new child elements, and new attributes.

6.4.14.2. Extended parameter mapping

No specific details of the scheme for encoding and passing parameter data are defined within this specification. Where parameters are passed on remote subflow invocation using the workflow Interoperability Specification (interface four), specifications are provided for the mapping of such parameters (for example into wf-XML exchanges) using the operations within the concrete syntax specification for interoperability. Any local scheme for parameter mapping and encoding is vendor defined on a product-by-product basis and lies outside the scope of this specification.
7. XML Process Definition Language

7.1. Elements Common for Multiple Entities

7.1.1. Node Graphics Info

NodeGraphicInfo is an optional entity that can be used by a tool to describe graphical information. Each graphical node in XPDL (Activity, Pool, Lane, Artifact) has a list of Node Graphics Info, one for each tool that has saved the corresponding information in the XPDL file. If a tool chooses to use the Node Graphics Info, it should select a tool id, which can be the name of the tool. Therefore multiple tools can work using the same XPDL file and displaying the process with a different presentation layout.

```xml
<xsd:element name="NodeGraphicsInfo">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Coordinates" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="ToolId" type="xsd:string" use="optional"/>
    <xsd:attribute name="IsVisible" type="xsd:boolean" use="optional" default="true"/>
    <xsd:attribute name="Page" type="xsd:NMTOKEN" use="optional"/>
    <xsd:attribute name="LaneId" type="xsd:NMTOKEN" use="optional"/>
    <xsd:attribute name="Height" type="xsd:double" use="optional"/>
    <xsd:attribute name="Width" type="xsd:double" use="optional"/>
    <xsd:attribute name="BorderColor" type="xsd:string" use="optional"/>
    <xsd:attribute name="FillColor" type="xsd:string" use="optional"/>
    <xsd:attribute name="Shape" type="xsd:string" use="optional"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>

<xsd:element name="Coordinates">
  <xsd:annotation>
    <xsd:documentation>BPMN and XPDL</xsd:documentation>
  </xsd:annotation>
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="XCoordinate" type="xsd:double" use="optional"/>
    <xsd:attribute name="YCoordinate" type="xsd:double" use="optional"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Border Color</td>
<td>Color of the border, expressed as a string.</td>
</tr>
<tr>
<td>Coordinates</td>
<td>X and Y coordinates of node’s upper left corner (bounding box).</td>
</tr>
<tr>
<td>Fill Color</td>
<td>Color of the fill, expressed as a string.</td>
</tr>
<tr>
<td>Height</td>
<td>Height of the node.</td>
</tr>
<tr>
<td>LaneId</td>
<td>If the node is in a Lane, this is the Id of the Lane.</td>
</tr>
</tbody>
</table>
## 7.1.2. Extended Attributes

Extended Attributes can be used in all entities. They allow vendors to extend the functionality of this specification to meet individual product needs. A vendor can use extended attributes in two manners:

a- The anonymous extended attribute provides a name and a value for the extension without the need to qualify the extension with a namespace.

b- Namespace qualified extensions can be used to extend XPDL elements by adding child elements or by adding attributes. Namespace qualified extensions can be validated against a vendor provided schema (see 7.2.1.1 Vendor extensions).

```xml
<xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>

<xsd:complexType name="ExtendedAttributesType">
  <xsd:sequence>
    <xsd:element ref="xpdl:ExtendedAttribute" minOccurs="0" maxOccurs="unbounded"/>
    <xsd:any namespace="##other" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
  </xsd:sequence>
  <xsd:anyAttribute namespace="##other" processContents="lax"/>
</xsd:complexType>
```

### 7.1.2.1. Anonymous Extended Attribute

The anonymous extended attributes use the ExtendedAttribute element that can be used to add an extension with a name and a value.

```xml
<xsd:element name="ExtendedAttribute">
  <xsd:complexType mixed="true">
    <xsd:choice minOccurs="0" maxOccurs="unbounded">
      <xsd:any processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
    </xsd:choice>
    <xsd:attribute name="Name" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Value" type="xsd:string"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>Description</th>
<th>Tool Id</th>
<th>Tool id. This will normally be the tool name.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is Visible</td>
<td>True indicates node should be shown.</td>
</tr>
<tr>
<td></td>
<td>Page</td>
<td>The name of the page on which this node should be displayed.</td>
</tr>
<tr>
<td></td>
<td>Shape</td>
<td>Shape, expressed as a string: used to override BPMN shapes</td>
</tr>
<tr>
<td></td>
<td>Width</td>
<td>Width of the node.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>Name</th>
<th>Used to identify the Extended Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Value</td>
<td>Value of the extension.</td>
</tr>
</tbody>
</table>

Table 2: Extended Attributes
7.1.2.2. Namespace Qualified Extensions

In order for a tool to add namespace-qualified extensions, it first needs to extend the XPDL schema to add the extensions in the places in which the XPDL schema allows the tool to add extensions. The new generated schema should contain in addition to the XPDL namespace the tool namespace. The resulting schema can be used in addition to the XPDL schema to validate XPDL 2.0 files. The extension places are marked in the XPDL schema by [namespace="##other" processContents="lax"].

In addition, the tool should include the namespace, and it should add the VendorExtension section in XPDL (see 7.2.1.1 Vendor extensions), which contains a URI reference to the extended schema.

A child element can be added to a XPDL element, by adding a child element to the ExtendAttributes under the XPDL element. An attribute to a XPDL element can also be added by just qualifying it by the vendor namespace.

7.1.3. Formal Parameters

Formal parameters can be used as attributes in process and application. They are passed during invocation and return of control (e.g. of an invoked application). These are the invocation parameters.

<table>
<thead>
<tr>
<th>Description</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>Data type of the formal parameter. See Section 7.12</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>Textual description of the formal parameter</td>
<td></td>
</tr>
</tbody>
</table>
7.1.3.1. Parameter passing semantics

The parameter passing semantics is defined as:

(a) Any read-only formal parameters (IN) are initialised by the value of the corresponding actual parameter in the call (an expression). This is pass-by-value semantics.

(b) Any read/write formal parameters (INOUT) are initialised by the value of the corresponding actual (passed) parameter, which must be the identifier of a relevant data field entity. On completion of the process, the value of the formal out parameter is copied back to the original actual parameter (which must be the identifier of a relevant data field entity). This is copy-restore semantics.

(c) Any write-only formal parameters (OUT) are initialised to zero (strings will be set to the empty string, complex data will have each element set to zero). On completion of the process, the value of the formal out parameter is copied back to the original actual parameter (which must be the identifier of a relevant data field entity). This is zero-restore semantics.

7.1.3.2. Concurrency semantics

Copying and restoring of parameters are treated as atomic operations; to avoid access conflicts from concurrent operations on relevant data field within the process instance these operations are serialized. Between copy and restore of (c) no locking is assumed and the returned parameter value will overwrite the local value (of the particular relevant data field item) at the time of the return call.

7.1.3.3. Formal-actual parameter mapping

The mapping of actual to formal parameters during invocation is defined by a parameter map list. The actual parameters are mapped 1:1 to the formal parameters in sequence, i.e. the first actual maps to the first formal, the second actual maps to the second formal etc. Type compatibility is required within the definitions and may be enforced by the runtime system. The effects of violation are locally defined and do not form part of this specification.

In case the actual parameter is an expression, the expression is evaluated and buffered by the engine, and the content of this buffer is used for formal-actual mapping. How the buffering and mapping is performed is outside the scope if this document.

7.1.4. External Reference

ExternalReference is a reference to an external definition of an entity. It can be used in DataTypes, Participant, and Application.

```xml
<xsd:element name="ExternalReference">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
```
Example 1: A FormalParameter that is defined by an XML schema:

```xml
<FormalParameter Id="PO">
  <DataType>
    <ExternalReference location="http://abc.com/schemas/po.xsd"/>
  </DataType>
  <Description>PO specification for abc.com</Description>
</FormalParameter>
```

Example 2: A DataField defined by a Java class:

```xml
<DataField Id="PO" Name="PurchaseOrder" IsArray="FALSE">
  <DataType>
    <ExternalReference location="com.abc.purchases.PO"/>
  </DataType>
  <Description>PO specification for abc.com</Description>
</DataField>
```

7.1.4.1. Web Services

An activity in a process may invoke a web service. The ExternalReference element may be used as a reference to applications and data types that are defined in Web Service (WSDL) documents.

Example 3: A DataField whose data type is defined in a WSDL document:

```xml
<DataField Id="abcPO" Name="abcPurchaseOrder" IsArray="False">
  <DataType>
    <ExternalReference xref="PO" location="http://abc.com/services/poService.wsdl" namespace="poService/definitions/types"/>
  </DataType>
</DataField>
```

Example 4: An Application that is defined as an operation in a WSDL document:

```xml
<Application Id="placeOrder"/>
  <ExternalReference location="http://abc.com/PO/services/poService.wsdl" xref="PlaceOrder" namespace="http://abc.com/services/poService.wsdl/definitions/portType"/>
</Application>
```

7.1.5. Property

A Property is the BPMN equivalent to a Data Field. (In the future these two elements may be unified).
Modeler-defined Properties MAY be added to a Process. These Properties are “local” to the Process. All Tasks, Sub-Process objects, and Sub-Processes that are embedded SHALL have access to these Properties. The fully delineated name of these properties are “<processname>.<property name>” (e.g., “Add Customer.Customer Name”). If a process is embedded within another Process, then the fully delineated name SHALL also be preceded by the Parent Process name for as many Parents there are until the top level Process.

Modeler-defined Properties MAY be added to an activity. These Properties are “local” to the activity. These Properties are only for use within the processing of the activity. The fully delineated name of these properties is “<process name>.<activity name>.<property name>” (e.g., “Add Customer.Review Credit.Status”).

<table>
<thead>
<tr>

<td><strong>Id</strong></td>
</tr>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td><strong>Correlation</strong></td>
</tr>
</tbody>
</table>

| Table 5: Property |

### 7.1.6. Assignment

Data fields and BPMN properties may be explicitly assigned new values during the execution of a process. This may happen at the start or termination of a process or an activity. Assignments may also be associated with transitions/sequence flow, in which case the assignments are performed when the particular transition/outgoing sequence flow is chosen.
<xsd:documentation>rvalue expression of the assignment</xsd:documentation>
</xsd:annotation>
</xsd:element>
<xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
</xsd:sequence>
<xsd:attribute name="AssignTime" use="optional" default="Start">
<xsd:simpleType>
<xsd:restriction base="xsd:NMTOKEN">
<xsd:enumeration value="Start"/>
<xsd:enumeration value="End"/>
</xsd:restriction>
</xsd:simpleType>
</xsd:attribute>
</xsd:complexType>
</xsd:element>
<xsd:element name="Assignments">
<xsd:annotation>
<xsd:documentation>BPMN and XPDL</xsd:documentation>
</xsd:annotation>
<xsd:complexType>
<xsd:sequence>
<xsd:element ref="xpdl:Assignment" maxOccurs="unbounded"/>
<xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
</xsd:sequence>
</xsd:complexType>
</xsd:element>
</xsd:element>
</xsd:complexType>
</xsd:element>
</xsd:complexType>
</xsd:element>

<table>
<thead>
<tr>

</tr>
<tr>
<td>Expression</td>
<td>Rvalue expression in the scripting language specified for the package.</td>
</tr>
<tr>
<td>AssignTime</td>
<td>Specifies time of evaluation and assignment: Start or End of Process or Activity. Not relevant to transition/sequence flow.</td>
</tr>
</tbody>
</table>

Table 6: Assignment

### 7.1.7. Category

The modeler MAY add one or more Categories to various elements, such as Process, Activity and Transition; which can then be used for purposes such as reporting and analysis.

<table>
<thead>
<tr>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Id</td>
<td>Id of the category</td>
</tr>
<tr>
<td>Name</td>
<td>Name of Category</td>
</tr>
</tbody>
</table>
7.1.8. Message

The Message element is used in the definition of attributes for a Start Event, End Event, Intermediate Event, Task, and Message Flow.

```
<xsd:element name="Message">
  <xsd:complexType>
    <xsd:sequence minOccurs="0">
      <xsd:element ref="xpdl:Properties"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:attribute name="From" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="To" type="xsd:NMTOKEN" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Id</td>
<td>Id of the message</td>
</tr>
<tr>
<td>Name</td>
<td>Text description of the Message.</td>
</tr>
<tr>
<td>From</td>
<td>Must be the name of a Participant/Process.</td>
</tr>
<tr>
<td>Properties</td>
<td>A list of properties</td>
</tr>
<tr>
<td>To</td>
<td>Must be the name of a Participant/Process.</td>
</tr>
</tbody>
</table>

7.1.9. Web Service

```
<xsd:element name="WebService">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Participant" type="xsd:NMTOKEN" use="required">
      <xsd:annotation>
        <xsd:documentation>Must be the name of a Participant: Note, this will map to the BPEL4WS partnerLink.</xsd:documentation>
      </xsd:annotation>
    </xsd:attribute>
    <xsd:attribute name="Interface" type="xsd:string" use="required">
      <xsd:annotation>
        <xsd:documentation>(aka portType)</xsd:documentation>
      </xsd:annotation>
    </xsd:attribute>
    <xsd:attribute name="Operation" type="xsd:string" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```
Interface (aka portType) An Interface for the Web Service MUST be entered.

Operation One or more Operations for the Web Service MUST be entered. The syntax of the string is not defined in this specification.

Participant The name of a Participant/Process. Note, this will map to the BPEL4WS partnerLink.

Table 9: Web Service

7.1.10. Artifact

An Artifact is a graphical object that provides supporting information about the Process or elements within the Process. However, it does not directly affect the flow of the Process. Other examples of Artifacts include critical success factors and milestones.

```xml
<xsd:element name="Artifact">
  <xsd:annotation>
    <xsd:documentation>BPMN: Not further defined here.</xsd:documentation>
  </xsd:annotation>
  <xsd:complexType>
    <xsd:sequence minOccurs="0">
      <xsd:element ref="xpdl:Object" minOccurs="0" maxOccurs="unbounded"/>
      <xsd:element ref="xpdl:DataObject" minOccurs="0"/>
      <xsd:element ref="xpdl:NodeGraphicsInfo" minOccurs="0" />
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:attribute name="ArtifactType" use="required">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="DataObject"/>
          <xsd:enumeration value="Group"/>
          <xsd:enumeration value="Annotation"/>

#### 7.1.10.1. Object

Referred to by numerous other graphical elements.

```xml
<xsd:element name="Object">
  <xsd:complexType>
    <xsd:sequence minOccurs="0">
      <xsd:element ref="xpdl:Categories" minOccurs="0"/>
      <xsd:element ref="xpdl:Documentation" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

#### 7.1.10.2. DataObject

In BPMN, a Data Object is considered an Artifact and not a Flow Object. They are considered an Artifact because they do not have any direct affect on the Sequence Flow or Message Flow of the Process, but they do provide information about what the Process does. That is, how documents, data, and other objects are used and updated during the Process. While the name “Data Object” may imply an electronic document, they can be used to represent many different types of objects, both electronic and physical.

As an Artifact, Data Objects generally will be associated with Flow Objects. An Association will be used to make the connection between the Data Object and the Flow Object. This means that the behavior of the Process can be modeled without Data Objects for modelers who want to reduce clutter. The same Process can be modeled with Data Objects for modelers who want to include more information without changing the basic behavior of the Process.

In some cases, the Data Object will be shown being sent from one activity to another, via a Sequence Flow. Data Objects will also be associated with Message Flow. They are not to be confused with the message itself, but could be thought of as the “payload” or content of some messages.
In other cases, the same Data Object will be shown as being an input, then an output of a Process. Directionality added to the Association will show whether the Data Object is an input or an output. Also, the state attribute of the Data Object can change to show the impact of the Process on the Data Object.

```
<xsd:element name="DataObject">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Properties"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:attribute name="State" type="xsd:string" use="optional"/>
    <xsd:attribute name="RequiredForStart" type="xsd:boolean" use="required"/>
    <xsd:attribute name="ProducedAtCompletion" type="xsd:boolean" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

</tbody>
</table>

### 7.1.11. ConnectorGraphicsInfo

ConnectorGraphicsInfo is an optional entity that can be used by a tool to describe graphical information for connecting objects (SequenceFlow, MessageFlow, Associations). Each connector in XPDL has a list of Connector Graphics Info, one for each tool that has saved the corresponding information in the XPDL file. If a tool chooses to use the Connector Graphics Info, it should select a tool id, which can be the name of the tool. Therefore multiple tools can work using the same XPDL file and displaying the process with a different presentation layout.

```
<xsd:element name="ConnectorGraphicsInfo">
  <xsd:annotation>
    <xsd:documentation>BPMN and XPDL</xsd:documentation>
  </xsd:annotation>
  <xsd:complexType>
    <xsd:sequence minOccurs="0">|
      <xsd:element ref="xpdl:CoordinatesList" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="ToolId" type="xsd:NMTOKEN" use="optional"/>
    <xsd:attribute name="IsVisible" type="xsd:boolean" use="optional" default="true"/>
    <xsd:attribute name="Page" type="xsd:NMTOKEN" use="optional"/>
  </xsd:complexType>
</xsd:element>
```
7.2. Package Definition

It is possible to define several processes within one package, which may share the same tools and participants. We recommend creating one package per business process which should contain all the necessary processes as well as all the associated tools and participants, although it is not required. It is also possible to define just parts of one process definition or common parts of several processes within one package (e.g. a participant list or a application list).

```
<body>
<table border="1">
  <tr><th>Description</th></tr>
  <tr><td>BorderColor</td><td>Color of the border, expressed as a string.</td></tr>
  <tr><td>Coordinates</td><td>X and Y coordinates of a point in the path.</td></tr>
  <tr><td>CoordinatesList</td><td>A list of coordinates</td></tr>
  <tr><td>FillColor</td><td>Color of the border, expressed as a string.</td></tr>
  <tr><td>ToolId</td><td>Tool id. This will normally be the tool name.</td></tr>
  <tr><td>IsVisible</td><td>True indicates node should be shown.</td></tr>
  <tr><td>Page</td><td>The name of the page on which this node should be displayed.</td></tr>
  <tr><td>Shape</td><td>Shape, expressed as a string: used to override BPMN shapes</td></tr>
  <tr><td>Style</td><td>LineStyle.</td></tr>
</table>

Table 13: ConnectorGraphicsInfo

**Table 15: Package Definition Header – Attributes**

### 7.2.1.1. Vendor extensions

Vendor extension is used for vendors to define extensions and provide a schema and a description for the extensions. For details, see section 7.1.2.2 Namespace Qualified Extensions.

```xml
<xsd:element name="VendorExtension">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="ToolId" type="xsd:string" use="required"/>
    <xsd:attribute name="schemaLocation" type="xsd:anyURI" use="required"/>
    <xsd:attribute name="extensionDescription" type="xsd:anyURI" use="optional"/>
  </xsd:complexType>
</xsd:element>

<xsd:element name="VendorExtensions">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:VendorExtension" minOccurs="0" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
```
### ToolId
Identification of the tool adding this extension. It is the same value used in NodeGraphicsInfo ToolId. This value may be a URI.

### SchemaLocation
An URI indicating the location of the schema that can be used to validate the XPDL containing the extensions for the tool.

### ExtensionDescription
An URI indicating the location of a document describing the extensions provided by the schema in schemaLocation.

<table>
<thead>
<tr>
<th>Table 16: Vendor Extension -- Attributes</th>

</tr>
</tbody>
</table>

#### 7.2.2. Redefinable Header

The redefinable header covers those header attributes that may be defined in the definition header and may be redefined in the header of any process definition. In case of redefinition, the scope rules hold.

```xml
<xsd:element name="RedefinableHeader">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Author" minOccurs="0"/>
      <xsd:element ref="xpdl:Version" minOccurs="0"/>
      <xsd:element ref="xpdl:Codepage" minOccurs="0"/>
      <xsd:element ref="xpdl:Countrykey" minOccurs="0"/>
      <xsd:element ref="xpdl:Responsibles" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="PublicationStatus">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="UNDER_REVISION"/>
          <xsd:enumeration value="RELEASED"/>
          <xsd:enumeration value="UNDER_TEST"/>
        </xsd:restriction>
      </xsd:simpleType>
    </xsd:attribute>
    <xsd:attribute name="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

```xml
<xsd:element name="Author">
  <xsd:complexType>
    <xsd:simpleContent>
      <xsd:extension base="xsd:string">
        <xsd:attribute name="##other" processContents="lax"/>
      </xsd:extension>
    </xsd:simpleContent>
  </xsd:complexType>
</xsd:element>
```

```xml
<xsd:element name="Version">
  <xsd:complexType>
    <xsd:simpleContent>
      <xsd:extension base="xsd:string">
        <xsd:attribute name="##other" processContents="lax"/>
      </xsd:extension>
    </xsd:simpleContent>
  </xsd:complexType>
</xsd:element>
```
<xsd:element name="Codepage">
  <xsd:complexType>
    <xsd:simpleContent>
      <xsd:extension base="xsd:string">
        <xsd:anyAttribute namespace="##other" processContents="lax"/>
      </xsd:extension>
    </xsd:simpleContent>
  </xsd:complexType>
</xsd:element>

<xsd:element name="Countrykey">
  <xsd:complexType>
    <xsd:simpleContent>
      <xsd:extension base="xsd:string">
        <xsd:anyAttribute namespace="##other" processContents="lax"/>
      </xsd:extension>
    </xsd:simpleContent>
  </xsd:complexType>
</xsd:element>

<xsd:element name="Responsible">
  <xsd:complexType>
    <xsd:simpleContent>
      <xsd:extension base="xsd:string">
        <xsd:anyAttribute namespace="##other" processContents="lax"/>
      </xsd:extension>
    </xsd:simpleContent>
  </xsd:complexType>
</xsd:element>

<xsd:element name="Responsibles">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Responsible" minOccurs="0" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>

<tr>
<td>Link to entity participant. Participant, who is responsible for this workflow of this Model definition (usually an Organisational Unit or a Human). It is assumed that the responsible is the supervisor during run time. Default: Initiating participant.</td>
</tr>
</tbody>
</table>
7.2.3. Conformance Class Declaration

The conformance class declaration allows description of the conformance class to which the definitions in this model definition are restricted. The specified class applies to all the contained process definitions, unless it is re-defined locally at the process definition level.

```xml
<xsd:element name="ConformanceClass">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="GraphConformance" use="optional" default="NON_BLOCKED">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="FULL_BLOCKED"/>
          <xsd:enumeration value="LOOP_BLOCKED"/>
          <xsd:enumeration value="NON_BLOCKED"/>
        </xsd:restriction>
      </xsd:simpleType>
    </xsd:attribute>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>Description</th>
<th>Conformance Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULL-BLOCKED</td>
<td>The network structure is restricted to proper nesting of SPLIT/JOIN and loops.</td>
</tr>
<tr>
<td>LOOP-BLOCKED</td>
<td>The network structure is restricted to proper nesting of loops.</td>
</tr>
<tr>
<td>NON-BLOCKED</td>
<td>There is no restriction on the network structure. This is the default.</td>
</tr>
</tbody>
</table>

Table 18: Conformance Class Declaration

7.2.4. Script

The Script element identifies the scripting language used in XPDL expressions. A text expression may be used wherever an element is of type xsd:string. One could, for example, use an expression within Cost elements.

An expression composed of formatted XML (e.g., MathML) may be used within the the ActualParameter or Xpression element (used within a Transition Condition).

```xml
<xsd:element name="Script">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Type" type="xsd:string" use="required"/>
    <xsd:attribute name="Version" type="xsd:string" use="optional"/>
    <xsd:attribute name="Grammar" type="xsd:anyURI" use="optional"/>
  </xsd:complexType>
</xsd:element>
```
### 7.2.5. External Package Reference

External package reference allows referencing definitions in another Package definition or in other systems providing an Interface to the Process or Management system (e.g. a legacy Organisation Description Management Tool).

```
<xs:element name="ExternalPackage">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
      <xs:attribute name="href" type="xs:string"/>
      <xs:attribute name="Id" type="xs:NMTOKEN" use="optional"/>
      <xs:attribute name="Name" type="xs:string"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

<table>
<thead>
<tr>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Identifies the scripting language used in expressions. For consistency across implementations, when specifying a standard scripting language, it is recommended that the Type be selected from the following strings: text/javascript, text/vbscript, text/tcl, text/ecmascript, text/xml.</td>
</tr>
<tr>
<td>Version</td>
<td>This is the version of the scripting language.</td>
</tr>
<tr>
<td>Grammar</td>
<td>This is a reference to a document that specifies the grammar of the language. It could be, for example, an XML schema, a DTD, or a BNF.</td>
</tr>
</tbody>
</table>

**Table 19: Script**

### 7.3. Application Declaration

Application declaration is a list of all applications or tools required and invoked by the processes defined within the process definition or surrounding package. Tools may be defined (or, in fact, just named). This means, that the real definition of the tools is not necessary and may be handled by an object manager. The reason for this approach is the handling of multi-platform environments, where a different program (or function) has to be invoked for each platform. XPDL abstracts from the concrete implementation or environment (thus these aspects are not of interest at process definition time).

```
<xs:element name="Application">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="Name" type="xs:string"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

<table>

### 7.3.1. Invocation Parameters

An Application declaration may have parameter definitions for the (invocation) parameters and also use them within other entities.

Copying the invocation **IN** is treated as one atomic operation. The same holds for restoring the invocation **OUT**. Between these two operations no assumption is made about concurrency behaviour.

### 7.3.2. Application Types

Application Type contains several pieces of information required by common applications such as calling an EJB component or invoking a WebService. Support for a particular application type is not mandatory for the engine, but if the engine makes use of the listed technologies the additional information should be provided by Application Type.

#### 7.3.2.1. EJB

Application type that defines information required to call a method of an EJB component. An EJB application has additional restrictions for formal parameters: there can be a maximum of one **OUT** formal parameter, and if it exists it has to be the last formal parameter, also there should be no **INOUT** formal parameters. With these restrictions **IN**
formal parameters map directly to arguments of the method and the optional last OUT formal parameter becomes the return value of the method.

```xml
<xsd:element name="Ejb">
  <xsd:annotation>
    <xsd:documentation>Call EJB component -- There can be max one formal parameter that is OUT, if it exists it has to be the last formal parameter. no INOUT formal parameters</xsd:documentation>
  </xsd:annotation>
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="JndiName" type="xsd:string"/>
      <xsd:element name="HomeClass" type="xsd:string"/>
      <xsd:element name="Method" type="xsd:string"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>

<td>Home class fully qualified name</td>
</tr>
<tr>
<td>Method</td>
<td>Method that will be invoked</td>
</tr>
</tbody>
</table>

**Table 22: EJB Application Type**

### 7.3.2.2. Pojo

Application type that defines information required to call method on local Java class. Formal Parameters restrictions are the same as for EJB application type.

```xml
<xsd:element name="Pojo">
  <xsd:annotation>
    <xsd:documentation>Call method on Java class -- There can be max one formal parameter that is OUT, if it exists it has to be the last formal parameter. no INOUT formal parameters</xsd:documentation>
  </xsd:annotation>
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="Class" type="xsd:string"/>
      <xsd:element name="Method" type="xsd:string"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

</table>

**Table 23: POJO Application Type**
7.3.2.3. XSLT

Application that uses XSL transformation on formal parameters. The Application should have one IN and one OUT formal parameter, or if the transformation transforms the formal parameter into a document in the same schema the application can have one INOUT formal parameter.

```xml
<xsd:element name="Xslt">
  <xsd:annotation>
    <xsd:documentation>Execute Transformation -- Formal Parameters restrictions: one IN and one OUT formal parameters or only one INOUT formal parameter</xsd:documentation>
  </xsd:annotation>
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="location" type="xsd:anyURI"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>

7.5. Process Definition

The Process Definition defines the elements that make up a process. It contains definitions or declarations, respectively, for Activity and, optionally, for Transition, Application, and Process Relevant Data entities. Attributes may be specified for administration relevant data like author, and version; for runtime relevant data like priority; and for BPR and simulation relevant data.

A Process may run as an implementation of an activity of type subflow; in this case parameters may be defined as attributes of the process.

Where a process definition includes input parameters and is instantiated by means other than a subflow call (for example by local event) the method for initializing any input parameters is locally defined. In such circumstances any relevant data field associated with the instantiated process definition, which is included within the parameter list will be initialized to the value specified in the “default value” (where specified). Where relevant data field is not passed as an input parameter, or initialized by “default value” the result is undefined. Similarly where a subflow terminates...
abnormally without returning out parameter values to the calling process, the result is undefined.

In general the scope of the defined entity identifier and name is the surrounding entity. The identifier is unique in this scope. For the Process identifier and name the scope is the surrounding Package.

```xml
<xsd:element name="Process" type="xpdl:ProcessType"/>
<xsd:element name="WorkflowProcess" type="xpdl:ProcessType"/>

### 7.5.3. Activity Set/Embedded SubProcess

An activity set is a self-contained set of activities and transitions. Transitions in the set should refer only to activities in the same set and there should be no transitions into or out of the set. Activity sets can be executed by block activities (see Section 7.6.3). An Activity Set is re-usable; it may be referred to by more than one Block Activity.

```xml
<xsd:element name="ActivitySet">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Activities" minOccurs="0"/>
      <xsd:element ref="xpdl:Transitions" minOccurs="0"/>
      <xsd:element ref="xpdl:Object" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional">  
      <xsd:annotation>
        <xsd:documentation source="added to XPDL 2.0"/>
      </xsd:annotation>
    </xsd:attribute>
    <xsd:attribute name="AdHoc" type="xsd:boolean" use="optional" default="false">  
      <xsd:annotation>
        <xsd:documentation>BPMN: for Embedded subprocess</xsd:documentation>
      </xsd:annotation>
    </xsd:attribute>
    <xsd:attribute name="AdHocOrdering" use="optional" default="Parallel">  
      <xsd:annotation>
        <xsd:documentation>BPMN: for Embedded subprocess</xsd:documentation>
      </xsd:annotation>
    </xsd:attribute>
    <xsd:attribute name="AdHocCompletionCondition" type="xsd:string" use="optional">  
      <xsd:annotation>
        <xsd:documentation>BPMN: for Embedded subprocess</xsd:documentation>
      </xsd:annotation>
    </xsd:attribute>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```
7.5.4. **ProcessType in BPMN mapping to WS-BPEL**

ProcessType is an attribute that provides information about which lower level language the Pool will be mapped to. By default, the ProcessType is None (or undefined). A Private ProcessType MAY be mapped to an executable WS-BPEL process. An Abstract ProcessType is also called the public interface of a process (or other web services) and MAY be mapped to an abstract WS-BPEL process. A Collaboration ProcessType will have two Lanes that represent business roles (e.g., buyer or seller) and will show the interactions between these roles. These Pools MAY be mapped to languages such as ebXML or WS Choreography. If the Process is to be used to create a WS-BPEL document, then the attribute MUST be set to Private or Abstract.

7.5.5. **Status**

The Status of a Process is determined when the Process is being executed by a process engine. The Status of a Process can be used within Assignment Expressions.

The following states are recognized:

- None
- Ready,
- Active
- Cancelled
- Aborting
- Aborted
- Completing
- Completed

7.5.6. **SuppressJoinFailure**

This attribute is included for mapping to WS-BPEL. This specifies whether or not a WS-BPEL joinFailure fault will be suppressed for all activities in the WS-BPEL process.

</tbody>
</table>

*Table 34: ActivitySet*
7.5.7. EnableInstanceCompensation

This attribute is included for mapping to WS-BPEL. It specifies whether or not a compensation can be performed after the Process has completed normally.

7.5.8. AdHoc

AdHoc is a boolean attribute, which has a default of False. This specifies whether the Process is Ad Hoc or not. The activities within an Ad Hoc Process are not controlled or sequenced in a particular order; their performance is determined by the performers of the activities.

If the Process is Ad Hoc (the AdHoc attribute is True), then the AdHocOrdering attribute MUST be included. This attribute defines if the activities within the Process can be performed in Parallel or must be performed sequentially. The default setting is Parallel and the setting of Sequential is a restriction on the performance that may be required due to shared resources.

If the Process is Ad Hoc (the AdHoc attribute is True), then the AdHocCompletionCondition attribute MUST be included. This attribute defines the conditions when the Process will end.

7.6. Process Activity

The Activity Definition is used to define each elementary activity that makes up a process. Attributes may be defined to specify activity control information, implementation alternatives, performer assignment, runtime relevant information like priority, and data used specifically in BPR and simulation situations (and not used within enactment). In addition, restrictions on data access and to transition evaluation (e.g. Split and Join) can be described. Mandatory attributes are used to define the activity identifier and type; a small number of other attributes are optional but have common usage across all activity types. Other attribute usage depends upon the activity type as shown in the table below.

For the Activity identifier and name the scope is the surrounding process.

The activity description is used to describe several different activity types. All these activities share the same (common) general activity attributes, but the usage of other attributes, particularly participant and application assignment and the use of relevant data field may be specialized to the activity type. The following table identifies the usage of other attributes / entity types for the different activity types.

<table>
<thead>
<tr>
<th>Entity Types</th>

</tr>
</tbody>
</table>

Copyright © 2005 The Workflow Management Coalition
Notes on usage:

Transition restrictions, subflow, and route activities are described in the section on transitions. In general, normal transition restrictions may be declared at the level of the activity boundary within the surrounding process, whereas specialized flow conditions (subflow, or the internal part of a route activity) operate “internal” to the activity (but may reference activities within the surrounding process definition). The following diagram illustrates the generic structure of an activity and the above variants.

Where the implementation type is NONE, the activity is manually controlled and its completion must be explicitly signaled to the process or management system. Such activities might typically comprise instructions to the participant to undertake a non-automated task of some type and inform a supervisor when completed.

Relevant data field may (potentially) be referenced within any activity although its use in manual activities is undefined through the process definition. Where an activity is of type subflow any in-parameters passed to the called (sub-)process must have been declared as relevant data field within the calling data field or been inherited from the surrounding package. (Similar requirements apply to any out-parameters returned to the calling process.) Routing and block activities may refer to such data within conditional expressions within the join/split control logic.

</tbody>
</table>

#### 7.6.1. Execution Control Attributes

These are attributes of an Activity that allow the definition of various activity-specific features for Activity execution control. Refer to the Table for Process Activity.
Automation mode defines the degree of automation when triggering and terminating an activity. There are two automation modes:

- **Automatic mode** is fully controlled by the process or workflow engine, i.e. the engine proceeds with execution of the activity within the process automatically, as soon as any incoming transition conditions are satisfied. Similarly, completion of the activity and progression to any post activity conditional logic occurs automatically on termination of the final invoked application.

- **Manual mode** requires explicit user interaction to cause activity start or finish. In such systems the activity start and/or completion is as a result of explicit user action.

The automation modes can be specified independently for the start and end of an Activity.

### 7.6.2. Route Activity

The Route activity makes use of Transition restrictions (sub elements of Activity) to implement complex routing logic. Refer to the discussion at the beginning of section 7.6, Figure 7-1 and the section on Transition Restriction: section 7.6.9.

The Route Activity is a "dummy" Activity that permits the expression of "cascading" Transition conditions (e.g. of the type "IF condition-1 THEN TO Activity-1 ELSE IF condition-2 THEN TO Activity-2 ELSE Activity-3 ENDF"). Some vendors might implement "cascading" transition conditions directly without requiring an activity counterpart for a route; others might require it. Wherever possible vendors and process designers are encouraged to structure such cascading conditions as an XOR split from the outgoing activity. Certain transition combinations cannot be expressed within a single transition list from the outgoing activity or a single incoming list to an activity. These cases require the use of one or more dummy activities; examples are:

- Combination of XOR and AND split conditions on outgoing transitions from an activity.
- Combination of XOR and AND join conditions on incoming transitions to an activity
- Transitions involving conditional AND joins of a subset of threads, with continuation of individual threads

A route activity has neither a performer nor an application.

For simulation purposes the following simulation data values should be assumed: Duration 0, Cost 0, WorkingTime 0, WaitingTime 0. For Priority and Instantiation the maximum value should be assumed.

```xml
<xsd:element name="Route">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="GatewayType" use="optional" default="XOR">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="XOR"/>
          <xsd:enumeration value="OR"/>
          <xsd:enumeration value="Complex"/>
          <xsd:enumeration value="AND"/>
        </xsd:restriction>
      </xsd:simpleType>
    </xsd:attribute>
    <xsd:attribute name="Instantiate" type="xsd:boolean" use="optional" default="false"/>
    <xsd:attribute name="MarkerVisible" type="xsd:boolean" use="optional" default="false"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```
7.6.2.1. Gateway Activity

BPMN Gateway activities are represented by Route Activities, using three new attributes:

- GatewayType
- Instantiate
- MarkerVisible

Note that GatewayType is included as an optional supplement to TransitionRestrictions (see section 7.6.9).

7.6.2.2. Examples of Gateways and their Representation

7.6.2.2.1. XOR Gate – Data based

7.6.3. Block Activity

A block activity executes an ActivitySet or self-contained activities/transitions map. From the Block Activity execution proceeds to the first activity in the set and continues within the set until it reaches an exit activity (an activity with no output transitions). Execution then returns to follow the output transitions of the block activity.

A block activity/embedded subprocess call is transactional if the parent Activity element has been specified as transactional.

7.6.4. Event Activity

An Event is something that “happens” during the course of a business process. These Events affect the flow of the Process and usually have a cause or an impact. The term “event” is general enough to cover many things in a business process. The start of an activity, the end of an activity, the change of state of a document, a message that arrives, etc., all could be considered events. However, BPMN has restricted the use of events to include only those types of events that will affect the sequence or timing of activities of a process. BPMN further categorizes Events into three main types: Start, Intermediate, and End. Start and most Intermediate Events have “Triggers” that define the cause for the event. There are multiple ways that these events can be triggered. End Events may define a “Result” that is a consequence of a Sequence Flow ending. There are multiple types of Results that can be defined.

Table 38: Event

#### 7.6.4.1. Start Event

As the name implies, the Start Event indicates where a particular Process will start. In terms of Sequence Flow, the Start Event starts the flow of the Process, and thus, will not have any incoming Sequence Flow—no Sequence Flow can connect to a Start Event.
There are many ways that a business process can be started (instantiated). The Trigger for a Start Event is designed to show the general mechanism that will instantiate that particular Process. There are six types of Start Events in BPMN: None, Message, Timer, Rule, Link, and Multiple.

```
<xsd:element name="StartEvent">
  <xsd:complexType>
    <xsd:choice minOccurs="0">
      <xsd:element ref="xpdl:TriggerResultMessage" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerTimer" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerRule" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerResultLink" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerMultiple" minOccurs="0"/>
    </xsd:choice>
    <xsd:attribute name="Trigger" use="required">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="None"/>
          <xsd:enumeration value="Message"/>
          <xsd:enumeration value="Timer"/>
          <xsd:enumeration value="Rule"/>
          <xsd:enumeration value="Link"/>
          <xsd:enumeration value="Multiple"/>
        </xsd:restriction>

<tr>
<td>TriggerResultMessage</td>
<td>A message arrives from a participant and triggers the start of the Process. See 7.6.4.4.5</td>
</tr>
<tr>
<td>TriggerRule</td>
<td>This type of event is triggered when the conditions for a rule such as “S&amp;P 500 changes by more than 10% since opening,” or “Temperature above 300C” become true. See 7.6.4.4.8</td>
</tr>
<tr>
<td>TriggerTimer</td>
<td>A specific time-date or a specific cycle (e.g., every Monday a 9am) can be set that will trigger the start of the Process. See 7.6.4.4.9</td>
</tr>
</tbody>
</table>

Table 39: Start Event Activity

7.6.4.2. Intermediate Event

Intermediate Events occur between a Start Event and an End Event. This is an event that occurs after a Process has been
started. It will affect the flow of the process, but will not start or (directly) terminate the process. Intermediate Events can be used to:
• Show where messages are expected or sent within the Process,
• Show delays are expected within the Process,
• Disrupt the Normal Flow through exception handling, or
• Show the extra work required for compensation.

```xml
<xsd:element name="IntermediateEvent">
    <xsd:complexType>
        <xsd:choice minOccurs="0">
            <xsd:element ref="xpdl:TriggerResultMessage" minOccurs="0"/>
            <xsd:element ref="xpdl:TriggerTimer" minOccurs="0"/>
            <xsd:element ref="xpdl:ResultError" minOccurs="0"/>
            <xsd:element ref="xpdl:ResultCompensation" minOccurs="0"/>
            <xsd:element ref="xpdl:TriggerRule" minOccurs="0"/>
            <xsd:element ref="xpdl:TriggerResultLink" minOccurs="0"/>
            <xsd:element ref="xpdl:TriggerIntermediateMultiple" minOccurs="0"/>
        </xsd:choice>
        <xsd:attribute name="Trigger" use="required">
            <xsd:simpleType>
                <xsd:restriction base="xsd:NMTOKEN">
                    <xsd:enumeration value="None"/>
                    <xsd:enumeration value="Message"/>
                    <xsd:enumeration value="Timer"/>
                    <xsd:enumeration value="Error"/>
                    <xsd:enumeration value="Cancel"/>
                    <xsd:enumeration value="Rule"/>
                    <xsd:enumeration value="Link"/>
                    <xsd:enumeration value="Compensation"/>
                    <xsd:enumeration value="Multiple"/>
                </xsd:restriction>
            </xsd:simpleType>
        </xsd:attribute>
        <xsd:attribute name="Implementation" use="optional" default="WebService">
            <xsd:simpleType>
                <xsd:restriction base="xsd:NMTOKEN">

### Description

<table>
<thead>
<tr>
<th>Implementation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResultCompensation</td>
<td>This is used for compensation handling—both setting and performing compensation. It calls for compensation if the Event is part of a Normal Flow. It reacts to a named compensation call when attached to the boundary of an activity. See 7.6.4.4.1</td>
</tr>
<tr>
<td>ResultError</td>
<td>This is used for error handling—both to set (throw) and to react to (catch) errors. It sets (throws) an error if the Event is part of a Normal Flow. It reacts to (catches) a named error, or to any error if a name is not specified, when attached to the boundary of an activity. See 7.6.4.4.2</td>
</tr>
<tr>
<td>Target</td>
<td>A Target MAY be included for the Intermediate Event. The Target MUST be an activity (Sub-Process or Task). This means that the Intermediate Event is attached to the boundary of the activity and is used to signify an exception or compensation for that activity.</td>
</tr>
</tbody>
</table>
Trigger

None, Message, Timer, Error, Cancel, Rule, Link, Compensation, Multiple. The None and Link Trigger MUST NOT be used when the Event is attached to the boundary of an Activity. The Multiple, Rule, and Cancel Triggers MUST NOT be used when the Event is part of the Normal Flow of the Process. The Cancel Trigger MUST NOT be used when the Event is attached to the boundary of a Transaction or if the Event is not contained within a Process that is a Transaction. “None” is used typically for Intermediate Events that are in the main flow of the Process. It is used for modeling methodologies that use Events to indicate some change of state in the Process.

Trigger Cancel

This type of Intermediate Event is used within a Transaction Sub-Process. This type of Event MUST be attached to the boundary of a Sub-Process. It SHALL be triggered if a Cancel End Event is reached within the Transaction Sub-Process. It also SHALL be triggered if a Transaction Protocol “Cancel” message has been received while the Transaction is being performed.

Trigger Intermediate Multiple

This means that there are multiple triggers listed. See 7.6.4.4.7

Trigger Result Link

If the Trigger is a Link, then the LinkId MUST be supplied. See 7.6.4.4.4

Trigger Result Message

A message arrives from a participant and triggers the Event. This causes the Process to continue if it was waiting for the message, or changes the flow for exception handling. In Normal Flow, Message Intermediate Events can be used for sending messages to a participant. If used for exception handling it will change the Normal Flow into an Exception Flow. See 7.6.4.4.5

Trigger Rule

This type of event is triggered when the conditions for a rule such as “S&P 500 changes by more than 10% since opening,” or “Temperature above 30°C” become true. See 7.6.4.4.8

Trigger Timer

A specific time-date or a specific cycle (e.g., every Monday at 9am) can be set that will trigger the Event. If used within the main flow it acts as a delay mechanism. If used for exception handling it will change the Normal Flow into an Exception Flow. See 7.6.4.4.9

Table 40: Intermediate Event Activity

7.6.4.3. End Event

As the name implies, the End Event indicates where a process will end. In terms of Sequence Flow, the End Event ends the flow of the Process, and thus, will not have any outgoing Sequence Flow—no Sequence Flow can connect from an End Event.
<xsd:enumeration value="Terminate"/>
<xsd:enumeration value="Multiple"/>

**Result**

None, Message, Error, Cancel, Compensation, Link, Terminate, Multiple.

‘None’ is used then the modeler does not display the type of Event. It is also used to show the end of a Sub-Process that ends, which causes the flow goes back to its Parent Process.

“Terminate” indicates that all activities in the Process should be immediately ended. This includes all instances of Multi-Instances. The Process is ended without compensation or event handling.

**ResultCompensation**

This type of End will indicate that a Compensation is necessary. The Compensation identifier will trigger an Intermediate Event when the Process is rolling back. See 7.6.4.4.1

**ResultError**

This type of End indicates that a named Error should be generated. This Error will be caught by an Intermediate Event within the Event Context. See 7.6.4.4.2

**TriggerResultLink**

A Link is a mechanism for connecting the end (Result) of one Process to the start (Trigger) of another. Typically, these are two Sub-Processes within the same parent Process. A Token arriving at Link End Event will immediately jump to its corresponding target Start or Intermediate Event. See 7.6.4.4.4

**ResultMultiple**

This means that there are multiple consequences of ending the Process. All of them will occur (e.g., there might be multiple messages sent). The attributes of the End Event will define which of the other types of Results apply. See 7.6.4.4.3

**Table 41: End Event Activity**

### 7.6.4.4. Common Elements Used in Start, Intermediate and End Events

#### 7.6.4.4.1. ResultCompensation

For an Intermediate Event within Normal Flow or an End Event:

If the Trigger is a Compensation, then the Id of the Activity that needs to be compensated MUST be supplied. This “throws” the compensation.

For an Intermediate Event attached to the boundary of an Activity: This Event “catches” the compensation. No further information is required. The Id of the activity the Event is attached to will provide the Id necessary to match the compensation event with the event that “threw” the compensation.

Compensation requires specific notation and is a special circumstance that occurs outside the Normal Flow of the Process. For this reason, the Compensation Intermediate Event does not have an outgoing Sequence Flow, but
instead has an outgoing directed Association. The target of this Association is the activity that will compensate for the work done in the source activity, and will be referred to as the Compensation Activity. The Compensation Activity is special in that it does not follow the normal Sequence Flow rules—as mentioned, it is outside the Normal Flow of the Process. This activity cannot have any incoming or outgoing Sequence Flow. The Compensation marker (as is in the Compensation Intermediate Event) will be displayed in the bottom center of the Activity to show this status of the activity.

```xml
<xsd:element name="ResultCompensation">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="ActivityId" type="xsd:NMTOKEN" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

### Table 42: Event ResultCompensation

<table>
<thead>
<tr>
<th>ActivityId</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>See Discussion above.</td>
</tr>
</tbody>
</table>

#### 7.6.4.4.2.ResultError

This is used for error handling—both to set (throw) and to react to (catch) errors. It sets (throws) an error if the Event is part of a Normal Flow (either Intermediate or End Event). It reacts to (catches) a named error, or to any error if a name is not specified, when attached to the boundary of an activity.

```xml
<xsd:element name="ResultError">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="ErrorCode" type="xsd:string" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

### Table 43: Event ResultError

<table>
<thead>
<tr>
<th>ErrorCode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>String designates the error Code.</td>
</tr>
</tbody>
</table>

#### 7.6.4.4.3.ResultMultiple

For an End Event:

This means that there are multiple consequences of ending the Process. All of them will occur (e.g., there might be multiple messages sent). The attributes of the End Event will define which of the other types of Results apply.

```xml
<xsd:element name="ResultMultiple">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:TriggerResultMessage" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerResultLink" minOccurs="0"/>
      <xsd:element ref="xpdl:ResultCompensation" minOccurs="0"/>
      <xsd:element ref="xpdl:ResultError" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
```
7.6.4.4.4. TriggerResultLink

For an End Event:
A Token arriving at Link End Event will immediately jump to its corresponding target Start or Intermediate Event, based on the LinkId.

For an Intermediate Event:
A Link is a mechanism for connecting an End Event (Result) of one Process to an Intermediate Event (Trigger) in another Process. Paired Intermediate Events can also be used as “Go To” objects within a Process.

For all Event Types:
The LinkId MUST be entered. The ProcessRef MUST be entered. The identified Process MAY be the same Process as that of the Link Event.

```xml
<xsd:element name="TriggerResultLink">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="LinkId" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="ProcessRef" type="xsd:NMTOKEN" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>LinkId</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Unique name for this link.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ProcessRef</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Id of the parent (embedding) process or Id of the subprocess.</td>
</tr>
</tbody>
</table>

7.6.4.4.5. TriggerResultMessage

For Start Event:
A message arrives from a participant and triggers the start of the Process.

For End Event:
This type of End indicates that a message is sent to a participant at the conclusion of the Process.

For Intermediate Event:
A message arrives from a participant and triggers the Event. This causes the Process to continue if it was waiting for the message, or changes the flow for exception handling. In Normal Flow, Message Intermediate Events can be used for sending messages to a participant. If used for exception handling it will change the Normal Flow into an Exception Flow.

```xml
<xsd:element name="TriggerResultMessage">
  <xsd:complexType>
  </xsd:complexType>
```
7.6.4.4.6. TriggerIntermediateMultiple

If the Trigger is a Multiple, then each Trigger on the list MUST have the appropriate data as specified for the attributes. The Trigger MUST NOT be of type None or Multiple.

```
<xsd:element name="TriggerIntermediateMultiple">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:TriggerResultMessage" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerTimer" minOccurs="0"/>
      <xsd:element ref="xpdl:ResultError" minOccurs="0"/>
      <xsd:element ref="xpdl:ResultCompensation" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerRule" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes"
        type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

Table 46: Event TriggerResultMessage

<table>
<thead>
<tr>
<th>Description</th>
<th>Message</th>
<th>See 7.1.8</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WebService</td>
<td>See 7.1.9</td>
</tr>
</tbody>
</table>

7.6.4.4.7. TriggerMultiple

If the Trigger attribute is a Multiple, then a list of two or more Triggers MUST be provided. Each Trigger MUST have the appropriate data. The Trigger MUST NOT be of type None or Multiple.

```
<xsd:element name="TriggerMultiple">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:TriggerResultMessage" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerTimer" minOccurs="0"/>
      <xsd:element ref="xpdl:TriggerRule" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes"
        type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

Table 47: Event TriggerIntermediate Multiple

| Description  | List of applicable triggers. |
Table 48: Event TriggerMultiple

7.6.4.4.8. TriggerRule
If the Trigger is a Rule, then a Rule MUST be entered.

For Intermediate Event:
This is only used for exception handling. This type of event is triggered when a Rule becomes true. A Rule is an expression that evaluates some Process data.

```xml
<xsd:element name="TriggerRule">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="RuleName" type="xsd:string" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

Table 49: Event TriggerRule

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RuleName A string which provides a way of locating the rule, or is the rule.</td>
</tr>
</tbody>
</table>

7.6.4.4.9. TriggerTimer
If the Trigger is a Timer, then a TimeDate MAY be entered. If a TimeDate is not entered, then a TimeCycle MUST be entered (see the attribute below).

```xml
<xsd:element name="TriggerTimer">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="TimeDate" type="xsd:string" use="optional"/>
    <xsd:attribute name="TimeCycle" type="xsd:string" use="optional"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

Table 50: Event TriggerTimer

<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimeDate String (Should be Date)</td>
</tr>
<tr>
<td>TimeCycle String (Should be expression designating repetitive occurrence based on time.</td>
</tr>
</tbody>
</table>

7.6.4.5. Examples of Events and their representation

![Diagram of an example event flow]
7.6.5. Implementation Alternatives

It is assumed that the execution of the Activity is atomic with respect to the data under control of the Process or Workflow engine. That implies that in the case of a system crash, an abort, or a cancellation of the Activity, the Relevant data field and the control data are rolled back (automatically or by other means), or an appropriate compensating activity is applied. (This does not necessarily hold for audit data.) This version of the specification does not include any specific controls over data synchronization or recovery (for example between execution, subflows or applications under execution.

An Activity may be implemented in one of four ways as described in the following table:

<table>
<thead>
<tr>
<th>Description</th>
<th>Implementation by manual procedures (i.e. not supported by workflow)</th>
</tr>
</thead>
<tbody>
<tr>
<td>No implementation</td>
<td></td>
</tr>
</tbody>
</table>

Table 51: Implementation Alternatives

<table>
<thead>
<tr>
<th>Implementation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProcessRef</td>
<td>Implementation by another process.</td>
</tr>
<tr>
<td>Tool</td>
<td>Implementation is supported by (one or more) application(s). Deprecated, see Task</td>
</tr>
<tr>
<td>Task</td>
<td>Implementation by a BPMN Task or Application(Tool). See section 7.6.5.3.</td>
</tr>
<tr>
<td>Subflow</td>
<td>Implementation by another process. Deprecated, see ProcessRef, Note that BlockActivity is used for ActivitySet/Embedded subprocess.</td>
</tr>
<tr>
<td>Reference</td>
<td>Implementation by BPMN reference. See section 7.6.5.5.</td>
</tr>
</tbody>
</table>

7.6.5.1. No Implementation

No Implementation means that the implementation of this Activity is not supported by Workflow using automatically invoked applications or procedures. Two Alternatives have been identified as to how this may be used:

It is a Manual Activity. In this case FinishMode value Manual is required.

It is an "implicit" activity, which is known to the Process Engine (e.g. by vendor-specific Extended Attributes) in terms of any processing requirements. An example is the Pre- and Post-processing Activities in a Process, which generate and clear hidden data when starting and terminating a process (e.g. managing the relationship to imaging system and archive). In this case the StartMode and FinishMode values Automatic are common.

(Note that application initiation may still be handled directly by the participant under local control in a manual activity; this lies outside the scope of the specification.)

```xml
<xsd:element name="No">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
```

7.6.5.2. Tool

Deprecated. See TaskApplication 7.6.5.3.8

7.6.5.3. Task

The Activity is implemented by one of the seven BPMN tasks or by an Application (Tool).

```xml
<xsd:element name="Task">
  <xsd:complexType>
    <xsd:choice>
      <xsd:element ref="xpdl:TaskService"/>
      <xsd:element ref="xpdl:TaskReceive"/>
      <xsd:element ref="xpdl:TaskManual"/>
      <xsd:element ref="xpdl:TaskReference"/>
      <xsd:element ref="xpdl:TaskScript"/>
      <xsd:element ref="xpdl:TaskSend"/>
      <xsd:element ref="xpdl:TaskUser"/>
      <xsd:element ref="xpdl:TaskApplication"/>
    </xsd:choice>
  </xsd:complexType>
</xsd:element>
```

7.6.5.3.1. TaskManual
<xsd:element name="TaskManual">
    <xsd:complexType>
        <xsd:sequence>
            <xsd:element ref="xpdl:Performers"/>
            <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
        </xsd:sequence>
    </xsd:complexType>
</xsd:element>

<table>
<thead>

<tr>
<td>WebService</td>
<td>Section 7.1.9</td>
</tr>
</tbody>
</table>

Table 58: Task User

7.6.5.3.8. TaskApplication (Tool)

The Activity is implemented by (one or more) tools. A tool may be an application program (link to entity Application); which may be invoked via IF3 - see the Workflow Client Application API (WAPI - Interface 2).

```xml
<xsd:element name="TaskApplication">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:choice minOccurs="0">
        <xsd:element ref="xpdl:ActualParameters"/>
        <xsd:element ref="xpdl:DataMappings"/>
      </xsd:choice>
      <xsd:element ref="xpdl:Description" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes"
        type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
  </xsd:complexType>
</xsd:element>
```
7.6.5.4. Subflow/ProcessRef

The Activity is refined as a subflow. The subflow may be executed synchronously or asynchronously. The subflow identifiers used are inherited from the surrounding Package declaration.

Subflow calls are transactional if the parent Activity has been defined that way. See Table 35.

In the case of asynchronous execution the execution of the Activity is continued after a process instance of the referenced Process Definition is initiated (in this case execution proceeds to any post activity split logic after subflow initiation. No return parameters are supported from such called processes. Synchronization with the initiated subflow, if required, has to be done by other means such as events, not described in this document. This style of subflow is characterized as chained (or forked) subflow operation.

In the case of synchronous execution the execution of the Activity is suspended after a process instance of the referenced Process Definition is initiated. After execution termination of this process instance the Activity is resumed. Return parameters may be used between the called and calling processes on completion of the subflow. This style of subflow is characterized as hierarchic subflow operation.

Table 60: Subflow
7.6.5. Reference

There may be times where a modeler may want to reference another Sub-Process that has been defined. If the two SubProcesses share the exact same behavior and properties, then by one referencing the other, the attributes that define the behavior only have to be created once and maintained in only one location.

There may be times where a modeler may want to reference another activity that has been defined. If the two (or more) activities share the exact same behavior, then by one referencing the other, the attributes that define the behavior only have to be created once and maintained in only one location.

Table 61: DataMapping

7.6.6. Performer Relationship

The relationship of the Activity to a (potential) performer is given by the Participant Assignment attribute. It provides a link to the entity Participant. Default: Any Participant.

The Participant identifiers used in the Performer attribute have either to be declared in the surrounding Process definition or are inherited from the surrounding Package declaration or coming from external packages.

The question whether the expression evaluation results in an empty set of performers or a non-unique performer is to be handled by the process or workflow management system at run time or, where defined, by the external resource repository or organizational model. The runtime resolution of both cases is outside the scope of this specification.

- In the first case (empty set) the engine may e.g. retry at a later time, or it may signal this to the supervisor of the process. The approach used is local to the WFMS and does not form part of this specification.
- The second case (non-unique) may arise where the performer definition is by function/skill type (defined as "Role") and/or is an organization unit, which is itself a container for a set of participants. In these situations the approach adopted for participant assignment is local to the WFMS and does not form part of this specification.

Common scenarios are:

- Where an activity includes multiple work items that may be implemented in parallel, separate work
items may be presented to a number of performers.

- In other situations the activity may be assigned according to a local load-balancing algorithm or presented to multiple potential performers in their work lists and assigned to the first accepting participant. (It is the responsibility of the engine to provide the appropriate behavior.)

- The assignment of an activity to an organizational unit (e.g. a department) may result in the activity being offered to all members of the organizational unit and assigned to the first accepting participant or allow the manager of the unit to redirect the activity to a designated departmental member.

In all cases the participant assignments defined within the meta-model and expressed in XPDL only relate Activities to defined Participants (including the use of expressions and defined Functions) and do not differentiate between cases where the defined Participant is atomic (e.g. a person) or not (e.g. a team). The local behavior of the engine and the resource repository or organizational model in handling these situations is not defined.

### 7.6.7. Deadline

```xml
<xsd:element name="Deadline">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="DeadlineDuration" type="xpdl:ExpressionType" minOccurs="0"/>
      <xsd:element name="ExceptionName" minOccurs="0">
        <xsd:complexType>
          <xsd:simpleContent>
            <xsd:extension base="xsd:string">
              <xsd:anyAttribute namespace="##other" processContents="lax"/>
            </xsd:extension>
          </xsd:simpleContent>
        </xsd:complexType>
      </xsd:element>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Execution">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="ASYNCHR"/>
          <xsd:enumeration value="SYNCHR"/>
        </xsd:restriction>
      </xsd:simpleType>
    </xsd:attribute>
    <xsd:attribute>
      <xsd:anyAttribute namespace="##other" processContents="lax"/>
    </xsd:attribute>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>Description</th>
<th>Execution</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ASYNCHR</strong></td>
<td>The deadline is to be raised asynchronously. This is an implicit AND SPLIT operation, where the activity continues and another thread is started following the named exception transition. Another deadline may occur on the same activity, because it continues running.</td>
</tr>
<tr>
<td><strong>SYNCHR</strong></td>
<td>The activity is completed abnormally and flow continues on the named exception transition.</td>
</tr>
</tbody>
</table>
### Deadline

Deadlines are used to raise an exception upon the expiration of a specific period of time.

Upon the arrival of a deadline, an exception condition is raised and the appropriate exception transitions are followed. If the deadline is synchronous, then the activity is terminated before flow continues on the exception path. If the deadline is asynchronous, then an implicit AND SPLIT is performed, and a new thread of processing is started on the appropriate exception transition. Asynchronous exceptions can cause side effects, and should be used carefully. Some of these side effects are discussed later in this section.

A sample deadline is below. In the sample, an asynchronous “notifyException” will be raised after 3 days. The activity will continue normally at this point. If the activity is still executing after 5 days it will be terminated and a “timeoutException” will be raised.

**Sample Deadline**

```xml
<Deadline Execution="ASYNCHR">
  <DeadlineDuration>3 days</DeadlineDuration>
  <ExceptionName>notifyException</ExceptionName>
</Deadline>

<Deadline Execution="SYNCHR">
  <DeadlineDuration>5 days</DeadlineDuration>
  <ExceptionName>timeoutException</ExceptionName>
</Deadline>
```

The syntax of the deadline duration is implementation dependent. The duration may be relative or absolute and may use relevant data field.

If a synchronous deadline occurs on a block activity or a subflow, stopping the activity includes stopping all the threads in the block, or the subflow and all its threads and nested subflows as well. From a modeling perspective, this can be treated as “immediate termination.” If an engine chooses to deviate from this, such as allowing an in-process manual activity to complete, it should document this behavior.

An asynchronous exception can be a powerful tool, allowing intermediate notification and graceful process termination by altering relevant data field. But an asynchronous exception can also create race conditions and possible side effects. For instance, the running activity could complete while the asynchronous exception is being processed. In addition, because an implicit split is performed, flow control can be complicated if the asynchronous exception processing joins back up with the deadline processing thread. Care must be taken by the designer to properly handle race conditions and avoid unwanted side effects.

### Simulation Information

<td>Specifies that the outgoing Transitions of the Activity are SPLIT-ed</td>
</tr>
</tbody>
</table>

#### Table 65: Transition Restrictions

#### 7.6.9.1. Join

A join describes the semantics of an activity with multiple incoming Transitions.

```xml
<xsd:element name="Join">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes"
        type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Type">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="AND"/>
          <xsd:enumeration value="XOR"/>
          <xsd:enumeration value="XOREVENT"/>
          <xsd:enumeration value="OR"/>
          <xsd:enumeration value="COMPLEX"/>
        </xsd:restriction>
      </xsd:simpleType>
    </xsd:attribute>
  </xsd:complexType>
</xsd:element>
```
### Type

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td>Join of (all) concurrent threads within the process instance with incoming transitions to the activity: Synchronization is required. The number of threads to be synchronized might be dependent on the result of the conditions of previous AND split(s). Equivalent to BPMN ‘OR’ gateway merge logic. BPMN ‘AND’ gateway merge logic requires all incoming transition threads to be synchronized, regardless of previous splits.</td>
</tr>
<tr>
<td>OR</td>
<td>See above.</td>
</tr>
<tr>
<td>XOR</td>
<td>Join for alternative threads: No synchronisation is required.</td>
</tr>
<tr>
<td>XOREVENT</td>
<td>Identical to XOR for merges.</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>This makes use of the attribute <strong>IncomingCondition</strong>. It determines which of the incoming transitions/Sequence Flow are required for the Process to continue. The expression may refer to process data and the status of the incoming Sequence Flow. For example, an expression may specify that any 3 out of 5 incoming Tokens will continue the Process. Another example would be an expression that specifies that a Token is required from Sequence Flow “a” and that a Token from either Sequence Flow “b” or “c” is acceptable. However, the expression should be designed so that the Process is not stalled at that location.</td>
</tr>
</tbody>
</table>

#### Table 66: Join

The AND join can be seen as a "rendezvous precondition" of the Activity; the activity is not initiated until the transition conditions on all incoming routes evaluate true.

The XOR join initiates the Activity when the transition conditions of any (one) of the incoming transitions evaluates true.

### 7.6.9.2. Split

A split describes the semantics where multiple outgoing Transitions for an Activity exist.

```xml
<xsd:element name="Split">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:TransitionRefs" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="OutgoingCondition" type="xsd:string"/> <xsd:anyAttribute namespace="#other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```
Transition Refs

A list of outgoing transitions from the Activity. Each transition is identified by its Id.
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td>Defines a number of possible concurrent threads represented by the outgoing Transitions of this Activity. If the Transitions have conditions the actual number of executed parallel threads is dependent on the conditions associated with each transition, which are evaluated concurrently. Note that the BPMN ‘AND’ gateway is a special case where none of the transitions (sequence flow gates) have conditions.</td>
</tr>
<tr>
<td>OR</td>
<td>Another BPMN variant of AND. Here the transitions may have conditions and multiple paths out may be chosen. The difference is that a default path may also be specified so that, in case none of the other paths are chosen, the default will be selected.</td>
</tr>
<tr>
<td>XOR</td>
<td>List of Identifiers of outgoing Transitions of this Activity, representing, alternatively executed transitions. The decision as to which single transition route is selected is dependent on the conditions of each individual transition as they are evaluated in the sequence specified in the list. The first TRUE condition (or no condition) ends the list evaluation. An OTHERWISE transition should be chosen if no prior transition is chosen. Equivalent to BPMN XOR data based Gateway.</td>
</tr>
<tr>
<td>XOR_EVENT</td>
<td>Similar to XOR except that none of the transitions have conditions and there can be no OTHERWISE transition. The target activities must be Tasks with the TaskType attribute set to Receive or Intermediate Events with the Trigger attribute set to Message, Timer, Rule, or Link. If one transition/Gate target is a Task, then an Intermediate Event with a Trigger Message MUST NOT be used as a target for another transition/Gate. That is, messages MUST be received by only Receive Tasks or only Message Events, but not a mixture of both for a given Gateway.</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>This makes use of the attribute OutgoingCondition. It determines which of the outgoing transitions/Sequence Flow will be chosen for the Process to continue. The expression may refer to process data and the status of the incoming Sequence Flow. For example, an expression may evaluate Process data and then select different sets of outgoing Sequence Flow, based on the results of the evaluation. However, The expression should be designed so that at least one of the outgoing Sequence Flow will be chosen.</td>
</tr>
</tbody>
</table>

An AND split with transitions having conditions may be referred to as "conditional AND", "multiple-choice OR", or "nonexclusive OR", respectively. The number of actual concurrent threads is determined at execution time when evaluating the conditions. Following such an AND split the process instance (or thread of the process instance) is forked into a number of separate execution threads which result from the transitions condition evaluation. (Note that no list of identifiers is required since all outgoing transitions from the activity are evaluated and no sequence is necessary.)

If within the AND_SPLIT or XOR_SPLIT there is a transition having condition OTHERWISE, then a two-step evaluation is performed. In the first step evaluation is made of all the Transitions except that within the OTHERWISE condition. If none of them (including those having no condition) evaluate to TRUE, then in the second step the OTHERWISE transition is evaluated (only one transition with an OTHERWISE clause is permitted in the list of outgoing transitions from an activity).

An OTHERWISE alternative can be used to guarantee that there is no undefined status from the Process execution (i.e. at least one outgoing transition from an activity will always occur).
7.6.10. Conformance Classes

There are Conformance Classes restricting the Activity-Transition Net.

The following Conformance Classes are defined in the package:

- **NON-BLOCKED**
  - There is no restriction for this class.

- **LOOP-BLOCKED**
  - The Activities and Transitions of a Process Definition form an acyclic graph (or set of disjoint acyclic graphs).

- **FULL-BLOCKED**
  - For each join (or respectively split) there is exactly one corresponding split (or respectively join) of the same kind. In an AND split no conditions are permitted; in a XOR split an unconditional or OTHERWISE Transition is required if there is a Transition with a condition (i.e. an undefined result of transition evaluation is not permitted).

```xml
<xsd:element name="ConformanceClass">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="GraphConformance" use="optional" default="NON_BLOCKED">
      <xsd:simpleType>
        <xsd:restriction base="xsd:NMTOKEN">
          <xsd:enumeration value="FULL_BLOCKED"/>
          <xsd:enumeration value="LOOP_BLOCKED"/>
          <xsd:enumeration value="NON_BLOCKED"/>
        </xsd:restriction>
      </xsd:simpleType>
      <xsd:anyAttribute namespace="##other" processContents="lax"/>
    </xsd:attribute>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>Graph Conformance</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULL, LOOP or NON</td>
<td>as discussed above.</td>
</tr>
</tbody>
</table>

*Table 68: ConformanceClass*

7.6.11. InputSets

The InputSets attribute defines the data requirements for input to the activity. Zero or more InputSets MAY be defined. Each InputSet is sufficient to allow the activity to be performed (if it has first been instantiated by the appropriate signal arriving from an incoming Sequence Flow).

One or more Inputs MUST be defined for each InputSet. An Input is an Artifact, usually a Document Object. Note that the Artifacts MAY also be displayed on the diagram and MAY be connected to the activity through an Association--however, it is not required for them to be displayed.

```xml
<xsd:element name="Input">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
```
<xsd:element name="Output">
    <xsd:complexType>
        <xsd:sequence>
            <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
        </xsd:sequence>
        <xsd:attribute name="ArtifactId" type="xsd:NMTOKEN" use="required"/>
        <xsd:anyAttribute namespace="##other" processContents="lax"/>
    </xsd:complexType>
</xsd:element>

Table 69: Input

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Artifact</td>
</tr>
<tr>
<td>Input</td>
</tr>
<tr>
<td>InputSet</td>
</tr>
</tbody>
</table>

7.6.12. OutputSets

The OutputSets attribute defines the data requirements for output from the activity. Zero or more OutputSets MAY be defined. At the completion of the activity, only one of the OutputSets may be produced--It is up to the implementation of the activity to determine which set will be produced. However, the IORules attribute MAY indicate a relationship between an OutputSet and an InputSet that started the activity.

One or more Outputs MUST be defined for each OutputSet. An Output is an Artifact, usually a Document Object. Note that the Artifacts MAY also be displayed on the diagram and MAY be connected to the activity through an Association--however, it is not required for them to be displayed.
<xsd:element name="OutputSet">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Output" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>

<xsd:element name="OutputSets">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:OutputSet" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>

</tr>
</tbody>
</table>

Table 70: Output

7.6.13. Transaction

A Sub-Process activity, whether it is independent (implemented by subflow) or embedded (block activity), can be set as being a Transaction, which will have a special behavior that is controlled through a transaction protocol (such as BTP or WSTransaction).

There are three basic outcomes of a Transaction:
- Successful completion: this will be shown as a normal Sequence Flow that leaves the Sub-Process.
- Failed completion (Cancel):
  When a Transaction is cancelled, then the activities inside the Transaction will be subjected to the cancellation actions, which could include rolling back the process and compensation for specific activities. Note that other mechanisms for interrupting a Sub-Process will not cause Compensation (e.g., Error, Timer, and anything for a non-Transaction activity). A Cancel Intermediate Event, attached to the boundary of the activity, will direct the flow after the Transaction has been rolled back and all compensation has been completed. The Cancel Intermediate Event can only be used when attached to the boundary of a Transaction activity. It cannot be used in any Normal Flow and cannot be attached to a non-Transaction activity. There are two mechanisms that can signal the cancellation of a Transaction:
  - A Cancel End Event is reached within the Transaction Sub-Process. A Cancel End Event can only be used within a Sub-Process that is set to a Transaction.
  - A Cancel Message can be received via the Transaction Protocol that is supporting the execution of the Sub-Process.
- Hazard: This means that something went terribly wrong and that a normal success or cancel is not possible. We are using an Error to show Hazards. When a Hazard happens, the activity is interrupted (without Compensation) and the flow will continue from the Error Intermediate Event.

The behavior at the end of a successful Transaction Sub-Process is slightly different than that of a normal Sub-Process. When each path of the Transaction Sub-Process reaches a non-Cancel End Event(s), the flow does not immediately move back up to the higher-level Parent Process, as does a normal Sub-Process. First, the transaction protocol must
verify that all the participants have successfully completed their end of the Transaction. Most of the time this will be true and the flow will then move up to the higher-level Process. But it is possible that one of the participants may end up with a problem that causes a Cancel or a Hazard. In this case, the flow will then move to the appropriate Intermediate Event, even though it had apparently finished successfully.

Note: The exact behavior and notation for defining Transactions is still an open issue. Refer to the section entitled “Open Issues” on page 243 of the BPMN 1.0 specification for a complete list of the issues open for BPMN.

```xml
<xsd:element name="Transaction">
    <xsd:complexType>
        <xsd:sequence>
            <xsd:element name="ExtendedAttributes"
                type="xpdl:ExtendedAttributesType" minOccurs="0"/>
        </xsd:sequence>
        <xsd:attribute name="TransactionId" type="xsd:string" use="required"/>
        <xsd:attribute name="TransactionProtocol" type="xsd:string" use="required"/>
        <xsd:attribute name="TransactionMethod" use="required">
            <xsd:simpleType>
                <xsd:restriction base="xsd:NMTOKEN">
                    <xsd:enumeration value="Compensate"/>
                    <xsd:enumeration value="Store"/>
                    <xsd:enumeration value="Image"/>
                </xsd:restriction>
            </xsd:simpleType>
        </xsd:attribute>
        <xsd:anyAttribute namespace="##other" processContents="lax"/>
    </xsd:complexType>
</xsd:element>
```

<table>

<td>TransactionProtocol</td>
<td>This identifies the Protocol (e.g., WS-Transaction or BTP) that will be used to control the transactional behavior of the Sub-Process.</td>
</tr>
</tbody>
</table>

Table 71: Transaction

### 7.6.14. Loop

The attributes of Tasks and Sub-Processes will determine if they are repeated or performed once. There are two types of loops: Standard and Multi-Instance.

A Standard Loop activity will have a boolean expression that is evaluated after each cycle of the loop. If the expression is still True, then the loop will continue. There are two variations of the loop, which reflect the programming constructs of while and until. That is, a while loop will evaluate the expression before the activity is performed, which means that the activity may not actually be performed. The until loop will evaluate the expression after the activity has been performed, which means that the activity will be performed at least once.

Multi-Instance loops reflect the programming construct foreach. The loop expression for a Multi-Instance loop is a numeric expression evaluated only once before the activity is performed. The result of the expression evaluation will be an integer that will specify the number of times that the activity will be repeated. There are also two variations of the Multi-Instance loop where the instances are either performed sequentially or in parallel.

```xml
<xsd:element name="Loop">
    <xsd:complexType>
        <xsd:choice>
            <xsd:element ref="xpdl:LoopStandard"/>
        </xsd:choice>
    </xsd:complexType>
</xsd:element>
```
<xsd:element ref="xpdl:LoopMultiInstance"/>
</xsd:choice>
<xsd:attribute name="LoopType" use="required">
  <xsd:simpleType>
    <xsd:restriction base="xsd:NMTOKEN">
      <xsd:enumeration value="Standard"/>
      <xsd:enumeration value="MultiInstance"/>
    </xsd:restriction>
  </xsd:simpleType>
</xsd:attribute>
<xsd:attribute>

    </xsd:attribute>
  </xsd:complexType>
7.7. Transition Information

The Transition Information describes possible transitions between activities and the conditions that enable or disable
them (the transitions) during execution. Further control and structure restrictions may be expressed in the Activity
definition.

A process definition is seen as a network of edges between the Activity nodes (i.e. as a process diagram). All edges are
directed and given by a pair of Activities:

(From node, to node).

The edges of the Activity net may be labelled by Transition conditions. A Transition condition for a specific edge
enables that transition if the condition evaluates to TRUE. If no routing condition is specified the Transition behaves as
if a condition with value TRUE is present.

If there are multiple incoming or outgoing ("regular", see below) Transitions of an Activity, then further options to
express control flow restrictions and condition evaluation semantics are provided in the Activity entity definition
(AND/XOR variants of SPLIT/JOIN).

A loop may be represented via a transition that returns to an Activity that was on a path that led to the transition.
Typically, at least one of the activities in the loop will have multiple outgoing transitions, one or more of which will
contain an exit condition from the loop.

For the identifiers and names defined in the Transition information the scope is the surrounding Process Definition.

It is possible to define or synchronize multiple (concurrent or alternative) control threads (split, join) and sequences of
Transitions between Activities (cascading Transitions/conditions).

<table>

#### 7.7.1. Condition

```xml
<html xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
     xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <xsd:element name="Condition">
    <xsd:complexType mixed="true">
      <xsd:choice minOccurs="0">
        <xsd:element name="Xpression" type="xpdl:ExpressionType"
                     minOccurs="0"/>
        <xsd:element name="Expression" type="xpdl:ExpressionType"
                     minOccurs="0"/>
      </xsd:choice>
      <xsd:attribute name="Type">
        <xsd:simpleType>
          <xsd:restriction base="xsd:NMTOKEN">
            <xsd:enumeration value="CONDITION"/>
            <xsd:enumeration value="OTHERWISE"/>
            <xsd:enumeration value="EXCEPTION"/>
            <xsd:enumeration value="DEFAULTEXCEPTION"/>
          </xsd:restriction>
        </xsd:simpleType>
      </xsd:attribute>
      <xsd:anyAttribute namespace="##other" processContents="lax"/>
    </xsd:complexType>
  </xsd:element>
</html>
```

- **Type**
  - **CONDITION**: Indicates that the transition is to be executed if its condition is satisfied.
  - **OTHERWISE**: Indicates that the transition is the default transition that is executed if no conditions are met.
  - **EXCEPTION**: Indicates that the transition is to be executed if there is an exception and its condition is satisfied.
  - **DEFAULTEXCEPTION**: Indicates that the transition is the default transition that is executed if there is an exception and no exception conditions are met.

### Table 74: Condition

#### 7.7.1.1. Exception Conditions

The Exception and DEFAULTEXCEPTION types allow you to specify branches that are taken only when an Exception is raised. The EXCEPTION type is equivalent to the CONDITION type and the DEFAULTEXCEPTION matches the OTHERWISE type. The Condition may contain either the name of an Exception or a more complex expression. Except for the deadlines, exceptions are raised in an engine-specific manner. Like regular transitions, exception transitions are traversed only after the "From" activity has completed. An exception usually indicates abnormal completion.

The following example illustrates a set of transitions from an activity that includes exceptions: branches 1 and 2 are
processed under normal conditions; branches 3 and 4 are processed if there is an exception.

```xml
<Transitions>
  <Transition Id="branch1" From="CheckBalance" To="ProcessRequest">
    <Condition Type="CONDITION">Balance > 1000</Condition>
  </Transition>
  <Transition Id="branch2" From="CheckBalance" To="InsufFunds">
    <Condition Type="OTHERWISE"/>
  </Transition>
  <Transition Id="branch3" From="CheckBalance" To="MessageDisplay">
    <Condition Type="EXCEPTION">ATMDownException</Condition>
  </Transition>
  <Transition Id="branch4" From="CheckBalance" To="SendAlarm">
    <Condition Type="DEFAULTEXCEPTION"/>
  </Transition>
</Transitions>
```

### 7.8. Message Flow

A Message Flow is used to show the flow of messages between two entities that are prepared to send and receive them. In BPMN, two separate Pools in the Diagram will represent the two entities. Thus, Message Flow MUST connect two Pools, either to the Pools themselves or to Flow Objects within the Pools. They cannot connect two objects within the same Pool.

```xml
<xsd:element name="MessageFlow">
  <xsd:complexType>
    <xsd:sequence minOccurs="0">
      <xsd:element ref="xpdl:Message" minOccurs="0"/>
      <xsd:element ref="xpdl:Object" minOccurs="0"/>
      <xsd:element ref="xpdl:ConnectorGraphicsInfo" minOccurs="0" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:attribute name="Source" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Target" type="xsd:NMTOKEN" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

</tr>
</tbody>
</table>

Table 75: MessageFlow
7.9. Association

An Association is used to associate information and Artifacts with Flow Objects. Text and graphical non-Flow Objects can be associated with the Flow Objects and Flow. An Association is also used to show the activities used to compensate for an activity.

An Association is also used to associate Data Objects with other objects. A Data Object is used to show how documents are used throughout a Process. Refer to section 7.1.10.2 for more information on Data Objects.

```xml
<xsd:element name="Association">
  <xsd:annotation>
    <xsd:documentation>BPMN</xsd:documentation>
  </xsd:annotation>
  <xsd:complexType>
    <xsd:sequence minOccurs="0">
      <xsd:element ref="xpdl:Object"/>
      <xsd:element ref="xpdl:ConnectorGraphicsInfo" minOccurs="0" maxOccurs="unbounded"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Source" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Target" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:attribute name="AssociationDirection" use="optional" default="None"/>
    <xsd:attribute name="Description" type="xsd:NCName" use="optional"/>
    <xsd:attribute name="ConnectorGraphicsInfo" type="xsd:NonEmptyURIRef" use="optional"/>
    <xsd:attribute name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>

</thead>
<tbody>
<tr>
<td>None</td>
<td>To</td>
<td>Frm</td>
<td>Both</td>
<td>Short textual description of the Association.</td>
<td>Determines the source of an Association (any graphical object).</td>
<td>Used to identify the Association.</td>
</tr>
</tbody>
</table>
7.10. Participants

The Participant is one of the following types: resource set, resource, organizational unit, role, human, or system. A role and a resource are used in the sense of abstract actors. This definition is an abstraction level between the real performer and the activity, which has to be performed. During run time these abstract definitions are evaluated and assigned to concrete human(s) and/or program(s).

The scope of the identifier of a participant entity declaration in a minimal resource repository or organizational model is the surrounding entity (Process Definition or Process Model Definition) in which it is defined.

An external resource repository or organizational model may contain substantial additional information that complements the basic participant types presented in here.

```
<xsd:element name="Participant">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:ParticipantType"/>
      <xsd:element ref="xpdl:Description" minOccurs="0"/>
      <xsd:element ref="xpdl:ExternalReference" minOccurs="0"/>
      <xsd:element name="ExtendedAttributes"
                   type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

### Table 76: Association

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
</tr>
<tr>
<td>Target</td>
</tr>
</tbody>
</table>

### Table 77: Participant

</tr>
<tr>
<td>Extended Attributes</td>
</tr>
<tr>
<td>Id</td>
</tr>
<tr>
<td>Name</td>
</tr>
<tr>
<td>Participant Type</td>
</tr>
</tbody>
</table>

#### 7.10.1. Participant Entity Types

The Participant entity type attribute characterises the participant to be an individual, an organisational unit or an abstract resource such as a machine.

```
<xsd:element name="ParticipantType">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes"
                   type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
</xsd:element>
```
7.11. Relevant data field

Relevant data field represent the variables of a process or Package Definition. They are typically used to maintain decision data (used in conditions) or reference data values (parameters), which are passed between activities or subflow. This may be differentiated from application data, which is data managed or accessed wholly by the invoked applications and which is not accessible to the process or workflow management system. The relevant data field list defines all data objects, which are required by the process. The attribute `DataType` explicitly specifies all information needed for a process or workflow management system to define an appropriate data object for storing data, which is to be handled by an active instance of the process.

Relevant data field can be defined in a process and in a Package. The scopes differ in that the former may only be accessed by entities defined inside that process, while the latter may be used also e.g. to define the parameters of a process entity.

Where parameters are passed to a called subflow outside the current model definition (e.g. to support remote process invocation) it is the responsibility of the process designer(s) to ensure that data type compatibility exists across the parameter set.

```xml
    <xsd:element name="DataField">
        <xsd:complexType>
```
<xsd:sequence>
  <xsd:element ref="xpdl:DataType"/>
  <xsd:element name="InitialValue"
    type="xpdl:ExpressionType" minOccurs="0"/>
  <xsd:element ref="xpdl:Length" minOccurs="0"/>
  <xsd:element name="ExtendedAttributes"
    type="xpdl:ExtendedAttributesType" minOccurs="0"/>
</xsd:sequence>
<xsd:attribute name="Id" type="xsd:NMTOKEN" use="required"/>
<xsd:attribute name="Name" type="xsd:string" use="optional"/>
<xsd:attribute name="IsArray" use="optional" default="FALSE">
  <xsd:simpleType>
    <xsd:restriction base="xsd:NMTOKEN">
      <xsd:enumeration value="TRUE"/>
      <xsd:enumeration value="FALSE"/>
    </xsd:restriction>
  </xsd:simpleType>
</xsd:attribute>
<xsd:attribute name="Correlation" type="xsd:boolean" use="optional" default="false"/>
</xsd:complexType>
</xsd:element>

<DataFields>
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:DataField"
        minOccurs="0" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes"
        type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>

(DataType)
  <xsd:complexType>
    <xsd:group ref="xpdl:DataTypes"/>
  </xsd:complexType>
</xsd:element>

<Length>
  <xsd:complexType>
    <xsd:simpleContent>
      <xsd:extension base="xsd:string">
        <xsd:anyAttribute namespace="##other" processContents="lax"/>
      </xsd:extension>
    </xsd:simpleContent>
  </xsd:complexType>
</xsd:element>

<table>

<td></td>
</tr>
</tbody>
</table>
Data types consist of a set of standard types that may be used as part of the data specification of relevant data field, formal parameters, and Processes. You can also declare a new data type within a TypeDeclaration and use it wherever the standard data types are used. A data type may be selected from the following set of types.

Table 79: Relevant data field

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Array</td>
<td>Indicates if it is an array</td>
</tr>
<tr>
<td>Length</td>
<td>The length of the data</td>
</tr>
<tr>
<td>Name</td>
<td>Text used to identify the relevant data field</td>
</tr>
<tr>
<td>Correlation</td>
<td>Used in BPMN mapping to BPEL. Allows eventual integration of Property 7.1.5 and DataField.</td>
</tr>
</tbody>
</table>

Table 80: Standard Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array Type</td>
<td>A fixed size set of data all of the same data type (deprecated).</td>
</tr>
<tr>
<td>Basic Type</td>
<td>A simple type: STRING, INTEGER, FLOAT, DATETIME, REFERENCE, BOOLEAN, or PERFORMER.</td>
</tr>
<tr>
<td>Declared Type</td>
<td>A reference to a data type declared in a TypeDeclaration element.</td>
</tr>
<tr>
<td>Enumeration Type</td>
<td>A set of legal values of a variable or parameter (deprecated).</td>
</tr>
<tr>
<td>ExternalReference</td>
<td>A reference to a type defined in an external document. See Section 7.1.4</td>
</tr>
<tr>
<td>List Type</td>
<td>An unbounded set of data all of the same data type (deprecated).</td>
</tr>
<tr>
<td>Record Type</td>
<td>A set of members that may be of different types (deprecated).</td>
</tr>
<tr>
<td>SchemaType</td>
<td>A data type defined using an XML schema.</td>
</tr>
<tr>
<td>Union Type</td>
<td>A set of members only one of which will be used for an instance of the data (deprecated).</td>
</tr>
</tbody>
</table>

7.12.1. Basic Data Types

```xml
<xsd:element name="BasicType">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
```
**Complex Data Types**

XPDL permits the definition of complex data types such as arrays, records, unions, enumerations, and lists. Complex data types are defined using the SchemaType. The RecordType, UnionType, EnumerationType, ArrayType, and ListType, which were used in the past to define complex data, are now deprecated. They have been left in the xpdl schema for compatibility with previous versions.

### 7.12.2.1. Schema Type

The SchemaType allows users to define a data type using XML schema syntax. It may also be used to define an XML string that should conform to the schema.

```xml
<xs:element name="SchemaType">
  <xs:complexType>
    <xs:sequence>
      <xs:any namespace="##other" minOccurs="0" maxOccurs="unbounded"/>
      <xs:element name="ExtendedAttributes"
        type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

---

**Table 81: Basic Data Types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRING</td>
<td>A finite-length sequence of characters</td>
</tr>
<tr>
<td>FLOAT</td>
<td>A floating point or double precision number. The maximum size of the number is not specified in XPDL.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>A number represented by an optional sign followed by a finite-length sequence of decimal digits. The maximum size of the integer is not specified in XPDL.</td>
</tr>
<tr>
<td>REFERENCE</td>
<td>A reference to an external data type – now deprecated. The ExternalReference is the recommended way to refer to an external data type.</td>
</tr>
<tr>
<td>DATETIME</td>
<td>A specific instant of time. The date format is not specified within XPDL.</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>A data instance of a Boolean type is one having one of the values TRUE or FALSE. The internal representation of these values is not defined in the XPDL.</td>
</tr>
<tr>
<td>PERFORMER</td>
<td>A data instance of a performer type is one having a value of a declared participant.</td>
</tr>
</tbody>
</table>
The following, for example, could describe a C++ or Java class, a C structure, or an XML string:

```xml
<SchemaType>
  <schema xmlns="http://www.w3.org/2000/10/XMLSchema">
    <element name="PO">
      <complexType>
        <sequence>
          <element name="CustomerName" type="string"/>
          <element name="Address" type="string"/>
          <element name="OrderNumber" type="string"/>
        </sequence>
      </complexType>
    </element>
  </schema>
</SchemaType>
```

### 7.12.2.2. Record Type

```xml
<xsd:element name="RecordType">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Member" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

### Member

<table>
<thead>
<tr>
<th>Description</th>
<th>Data type of a member. See Table 80: Standard Data Types.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Member</td>
<td>A field in the record.</td>
</tr>
</tbody>
</table>

### Table 82: Record Type

#### 7.12.2.3. Union Type

```xml
<xsd:element name="UnionType">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:Member" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

```xml
<xsd:element name="Member">
  <xsd:complexType>
    <xsd:group ref="xpdl:DataTypes"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```
7.12.2.4. Enumeration Type

<xsd:element name="EnumerationType">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element ref="xpdl:EnumerationValue" maxOccurs="unbounded"/>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>

<xsd:element name="EnumerationValue">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Name" type="xsd:NMTOKEN" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>

<table>
<thead>
<tr>
<th>Description</th>
<th>enumeration value</th>
<th>An element that represents one of the values in an enumeration.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td></td>
<td>The name of the value.</td>
</tr>
</tbody>
</table>

Table 84: Enumeration Type

7.12.2.5. Array Type

<xsd:element name="ArrayType">
  <xsd:complexType>
    <xsd:group ref="xpdl:DataTypes"/>
    <xsd:attribute name="LowerIndex" type="xsd:NMTOKEN" use="required"/>
    <xsd:attribute name="UpperIndex" type="xsd:NMTOKEN" use="required"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>

<table>
<thead>
<tr>
<th>Description</th>
<th>DataTypes</th>
<th>The data type of array entries. See Table 80: Standard Data Types.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Lower Index</td>
<td>The lower bound of an ArrayType.</td>
</tr>
<tr>
<td></td>
<td>Upper Index</td>
<td>The upper bound of an ArrayType.</td>
</tr>
</tbody>
</table>

Table 85: Array Type

7.12.2.6. List Type

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataTypes</td>
</tr>
</tbody>
</table>

Table 86: List Type

7.12.3. Declared Data Types

It is possible to reuse a complex data definition wherever you can use a standard XPDL type. Define the data type under a TypeDeclaration and then refer to it using the DeclaredType data type.

7.12.3.1. Type Declaration

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataTypes</td>
</tr>
<tr>
<td>Description</td>
</tr>
<tr>
<td>ExtendedAttributes</td>
</tr>
<tr>
<td>Id</td>
</tr>
<tr>
<td>Name</td>
</tr>
</tbody>
</table>
To reuse aSchemaType to define a purchase order:

```xml
<TypeDeclarations>
  <TypeDeclaration Id="POType" Name="PurchaseOrder">
    <SchemaType>
      <schema xmlns="http://www.w3.org/2000/10/XMLSchema">
        <element name="PO">
          <complexType>
            <sequence>
              <element name="CustomerName" type="string"/>
              <element name="Address" type="string"/>
              <element name="OrderNumber" type="string"/>
            </sequence>
          </complexType>
        </element>
      </schema>
    </SchemaType>
  </TypeDeclaration>
</TypeDeclarations>
```

### 7.12.3.2. Declared Type

```xml
<xsd:element name="DeclaredType">
  <xsd:complexType>
    <xsd:sequence>
      <xsd:element name="ExtendedAttributes" type="xpdl:ExtendedAttributesType" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="Id" type="xsd:IDREF" use="required"/>
    <xsd:attribute name="Name" type="xsd:string" use="optional"/>
    <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>
</xsd:element>
```

<table>
<thead>
<tr>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Id</td>
<td>A reference to a data type declared in a TypeDeclaration.</td>
</tr>
<tr>
<td>Name</td>
<td>A name for the declared type</td>
</tr>
</tbody>
</table>

**Table 88: Declared Data Type**

Using the DeclaredType type you could, for example, define a number of POType variables.

```xml
<DataFields>
  <DataField Id="newPO">
    <DataType>
      <DeclaredType Id="POType"/>
    </DataType>
  </DataField>
  <DataField Id="checkedPO">
    <DataType>
      <DeclaredType Id="POType"/>
    </DataType>
  </DataField>
</DataFields>
```
8. Sample Process

This sample process was created to illustrate some of the features of XPDL and does not represent any real processes or necessarily the best way to accomplish the process. The XPDL in the example was generated by an Open Source Java Application that was created by Global 360/CapeVisions and edited to incorporate unsupported features and improve readability.

The process represents an order entry system in which an order enters the system as a formatted string. The Package is composed of a main process and two subprocesses. The following discussion includes a brief overview of these processes along with a discussion of some of the data types, extended attributes, and external references used in the sample. Finally the XPDL is displayed.

8.1. The Processes

8.1.1. The EOrder Main Process

The main process takes a formatted string as an input and returns a string that indicates whether the order was confirmed or rejected. It contains the following steps:

- The string is first converted to a complex data object. If an exception is caught (indicating that the string is incorrectly formatted), an alarm is raised and the order is rejected.
- The data is checked for accuracy.
- The process determines whether payment is via a purchase order or a credit card.
- Credit card orders are sent to a subprocess that authorizes the credit purchase.
- Purchase orders are validated by an application that checks the vendor’s record and authorizes the purchase amount.
- The order is entered into the database and an order number is issued.
- The next three activities happen in parallel:
  - An acceptance message is composed to return to the end user.
  - A subprocess is invoked asynchronously to fill the order.
  - An order confirmation email is sent to the end user. This activity is a special activity that is managed by the system. It uses ExtendedAttributes to specify the information the system needs for the email.
- If an order is rejected, either because it is inaccurate or cannot obtain authorization, a rejection message is composed, to return to the customer.

![Figure 8-1: EOrder Main Process](image-url)
8.1.2. The CreditCheck Subprocess

The CreditCheck subprocess sets up a CreditInfo object from the input parameters and then sends the information to a
credit card web service for authorization. The web service returns a status string that is converted to an OrderStatus
string and returned to the calling process.

![CreditCheck Subprocess Diagram]

8.1.3. The FillOrder Subprocess

This subprocess handles the shipping and billing of the order. This process includes a participant called a “Shipper”

- The first activity displays the order information to a Shipper who ships the items in the order and records the
  status of the line items. The application returns the status of the order -- whether it is complete or backordered.
  This activity includes some deadlines. If the activity is not completed within 3 days, a notifyException is
  thrown an alarm is raised. If the activity is still not completed within 5 days, a timeoutException is thrown and
  the order is canceled.
- The process then determines if it is a PO or credit order.
- PO orders are sent to the billing system and then an electronic invoice is created and stored on a server.
- Credit card orders are sent to the credit card web service for charging and then an electronic receipt is created
  and stored on a server.
- The last step sends the invoice or receipt to the customer as an attachment to an email message. It uses
  ExtendedAttributes to specify the information needed for the email.

![FillOrder Subprocess Diagram]

8.2. Type Declarations

A number of data types are defined for the process.

- An Order is defined in a separate schema document and declared using an ExternalReference.

```
<TypeDeclaration Id="Order" Name="Order">
  <ExternalReference
    location="http://wfmc.org/standards/docs/xpdl_sample/orderschema.xsd"/>
</TypeDeclaration>
```
The schema is:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    elementFormDefault="qualified" attributeFormDefault="unqualified">
  <xsd:element name="Order">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="Items">
          <xsd:complexType>
            <xsd:sequence>
              <xsd:element name="Item" maxOccurs="unbounded">
                <xsd:complexType>
                  <xsd:attribute name="itemNumber" type="xsd:integer" use="required"/>
                  <xsd:attribute name="itemQty" type="xsd:integer" use="required"/>
                </xsd:complexType>
              </xsd:element>
            </xsd:sequence>
          </xsd:complexType>
        </xsd:element>
      </xsd:sequence>
      <xsd:attribute name="accountNumber" type="xsd:integer" use="required"/>
      <xsd:attribute name="totalAmount" type="xsd:float" use="required"/>
      <xsd:attribute name="emailAddress" type="xsd:string" use="required"/>
      <xsd:attribute name="orderType" use="required">
        <xsd:simpleType>
          <xsd:restriction base="xsd:NMTOKEN">
            <xsd:enumeration value="PO"/>
            <xsd:enumeration value="Credit"/>
          </xsd:restriction>
        </xsd:simpleType>
      </xsd:attribute>
      <xsd:attribute name="cardType" use="required">
        <xsd:simpleType>
          <xsd:restriction base="xsd:NMTOKEN">
            <xsd:enumeration value="MC-VISA"/>
            <xsd:enumeration value="Discover"/>
            <xsd:enumeration value="AMEX"/>
          </xsd:restriction>
        </xsd:simpleType>
      </xsd:attribute>
    </xsd:complexType>
  </xsd:element>
</xsd:schema>
```

- An OrderStatus is directly defined using a SchemaType. It uses an XML schema to enumerate the valid strings that can represent the status.

```xml
<TypeDeclaration Id="OrderStatus" Name="OrderStatus">
  <SchemaType>
    <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
      elementFormDefault="qualified" attributeFormDefault="unqualified">
      <xsd:element name="Status">
        <xsd:simpleType>
          <xsd:restriction base="xsd:NMTOKEN">
            <xsd:enumeration value="ValidData"/>
            <xsd:enumeration value="InvalidData"/>
            <xsd:enumeration value="Accept"/>
            <xsd:enumeration value="BadCredit"/>
            <xsd:enumeration value="OverLimit"/>
            <xsd:enumeration value="BadDataFormat"/>
          </xsd:restriction>
        </xsd:simpleType>
      </xsd:element>
    </xsd:schema>
  </SchemaType>
</TypeDeclaration>
```
A CardType type uses an ExternalReference to the cardType attribute within the Order schema.

```
<TypeDeclaration Id="CardType" Name="CardType">
    <ExternalReference
        location="http://wfmc.org/standards/docs/xpdl_sample/orderschema.xsd"
        xref="cardType" namespace="orderschema/Order"/>
</TypeDeclaration>
```

A CreditInfo type uses an ExternalReference to a data type defined within a WSDL document.

```
<TypeDeclaration Id="CreditInfo" Name="CreditInfo">
    <ExternalReference
        location="http://wfmc.org/standards/docs/xpdl_sample/creditService.wsdl"
        xref="CreditInfo"/>
</TypeDeclaration>
```

Within the WSDL document, the type is defined as follows:

```
<types>
    <schema xmlns="http://www.w3.org/2001/XMLSchema">
        <element name="CreditInfo">
            <complexType>
                <sequence>
                    <element name="MerchantNumber"/>
                    <element name="AccountNumber"/>
                    <element name="Amount"/>
                    <element name="CardType"/>
                </sequence>
            </complexType>
        </element>
    </schema>
</types>
```

8.3. **ExtendedAttributes**

The process vendor defines several ExtendedAttributes to extend XPDL. The namespace, xmlns:xyz="http://www.xyzeorder.com/workflow", is designated for the ExtendedAttribute XML.

- There is an ExtendedAttribute to mark an activity as a SystemActivity, or one implemented by the process or workflow system. Three activities in the sample are so marked: email activities, alarm activities, and web service activities.

```
<ExtendedAttribute Name="SystemActivity" Value="WebService"/>
<ExtendedAttribute Name="SystemActivity" Value="Email"/>
<ExtendedAttribute Name="SystemActivity" Value="Alarm"/>
```

- There is an ExtendedAttribute to provide information for the email activity. It should be assumed that some of this information is supplied in the process modeling tool.

```
<ExtendedAttribute Name="Email">
    <xyz:Email to="emailAddress" subject="orderStatus">
        <xyz:Attachments>
            <xyz:Attachment>%%docURI</xyz:Attachment>
        </xyz:Attachments>
    </xyz:Email>
```

```
8.4. External References

The sample process makes an external reference to a WSDL document, creditService.wsdl, to define the applications used for processing a credit card purchase. (Section 8.2 illustrates the use of the ExternalReference element to import data types from external documents.)

```xml
<Application Id="getCreditAuthorization">
  <ExternalReference
    location="http://wfmc.org/standards/docs/xpdl_sample/creditService.wsdl"
    xref="GetCreditAuthorization"/>
</Application>
```

Within the WSDL document the applications are defined as operations:

```xml
<message name="creditInput">
  <part name="CreditInfo" element="tns:CreditInfo"/>
</message>

<message name="creditOutput">
  <part name="status" type="string"/>
</message>

<portType name="CreditPortType">
  <operation name="GetCreditAuthorization">
    <input message="tns:creditInput"/>
    <output message="tns:creditOutput"/>
  </operation>
  <operation name="ChargeCreditAccount">
    <input message="tns:creditInput"/>
    <output message="tns:creditOutput"/>
  </operation>
</portType>
```

8.5. Sample XPDL

```xml
<?xml version="1.0" encoding="UTF-8"?>
  <PackageHeader>
    <XPDLVersion>2.0</XPDLVersion>
    <Vendor>Global 360</Vendor>
    <Created>06/04/2005 14:50:58 PM</Created>
  </PackageHeader>
  <ConformanceClass GraphConformance="NON_BLOCKED"/>
  <Script Type="text/javascript"/>
  <TypeDeclarations>
    <TypeDeclaration Id="Order" Name="Order">
      <ExternalReference location="http://wfmc.org/standards/docs/xpdl_sample/orderschema.xsd"/>
    </TypeDeclaration>
    <TypeDeclaration Id="OrderStatus" Name="OrderStatus">
      <SchemaType>
        <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema" elementFormDefault="qualified" attributeFormDefault="unqualified">
          <xsd:simpleType>
            <xsd:restriction base="xsd:NMTOKEN">
              <xsd:enumeration value="ValidData"/>
              <xsd:enumeration value="InvalidData"/>
              <xsd:enumeration value="Accept"/>
              <xsd:enumeration value="BadCredit"/>
              <xsd:enumeration value="OverLimit"/>
              <xsd:enumeration value="BadDataFormat"/>
            </xsd:restriction>
          </xsd:simpleType>
        </xsd:schema>
      </SchemaType>
    </TypeDeclaration>
  </TypeDeclarations>
</Package>
```
<xsd:element name="Application">
